Package ‘bimets’

January 5, 2021

Type Package
Title Time Series and Econometric Modeling
Version 1.5.2
Date 2020-12-25
Maintainer Andrea Luciani <andrea.luciani@bancaditalia.it>
Author Andrea Luciani [aut, cre],
    Roberto Stok [aut],
    Bank of Italy [cph]
ByteCompile no
Description Time series analysis, (dis)aggregation and manipulation, e.g. time series extension, merge, projection, lag, lead, delta, moving and cumulative average and product, selection by index, date and year-period, conversion to daily, monthly, quarterly, (semi)annually. Simultaneous equation models definition, estimation, simulation and forecasting with coefficient restrictions, error autocorrelation, exogenization, add-factors, impact and interim multipliers analysis, conditional equation evaluation, endogenous targeting and model renormalization.
Depends R (>= 3.3), xts, zoo
Imports stats
LazyData true
License GPL-3
Encoding UTF-8
NeedsCompilation no
Repository CRAN
Date/Publication 2021-01-05 18:00:03 UTC

bimets-package

Description

bimets is a software framework developed by using R language and designed for time series analysis and econometric modeling, which allows creating and manipulating time series, specifying simultaneous equation models of any size by using a kind of high-level description language, and performing model estimation, simulation and forecasting.

In addition, bimets computational capabilities provide many tools to pre-process data and post-process results, designed for statisticians and economists. These operations are fully integrated with the R environment.

The package can be installed and loaded in R with the following commands (with R> as the R command prompt):

R> install.packages('bimets')
R> library(bimets)

TIME SERIES

bimets supports daily, weekly, monthly, quarterly, semiannual and yearly time series. Time series with a frequency of 24 and 36 periods per year are also supported. The time series are created by the TIMESERIES function.

Example:

R> # yearly time series
R> myTS <- TIMESERIES(1:10,START=as.Date('2000-01-01'),FREQ=1)

R> # monthly time series
R> myTS <- TIMESERIES(1:10,START=c(2002,3),FREQ='M')

The main bimets time series capabilities are:

- Indexing
- Aggregation / Disaggregation
- Manipulation
**Time Series Indexing**

The **bimets** package extends R indexing capabilities in order to ease time series analysis and manipulation. Users can access and modify time series data:

- **by date:** users can select and modify a single observation by date by using the syntax `ts["Date"]`, or multiple observations by using `ts["StartDate/EndDate"]`;

- **by year-period:** users can select and modify observations by providing the year and the period requested, i.e. `ts[[Year,Period]]`;

- **by observation index:** users can select and modify observations by simply providing the array of requested indexes, i.e. `ts[indexes]`;

**Example:**

```r
R> #create a daily time series
R> myTS <- TIMESERIES((1:100),START=c(2000,1),FREQ="D")
R> myTS[1:3] #get first three obs.
R> myTS["2000-01-12"] #get Jan 12, 2000 data
R> myTS["2000-02-03/2000-02-14"] #get Feb 3 up to Feb 14
R> myTS[[2000,14]] #get year 2000 period 14
R> myTS["2000-01-15"] <- NA #assign to Jan 15, 2000
R> myTS[[2000,42]] <- NA #assign to Feb 11, 2000
R> myTS[[2000,100]] <- c(-1,-2,-3) #extend time series starting from period 100
```

**Time Series Aggregation/Disaggregation**

The **bimets** package provides advanced (dis)aggregation capabilities, with several linear interpolation capabilities in disaggregation, and many aggregation functions (e.g. STOCK, SUM, AVE, etc.) while reducing the time series frequency.

**Example:**

```r
R> #create a monthly time series
R> myMonthlyTS <- TIMESERIES(1:100,START=c(2000,1),FREQ='M')
R> #convert to yearly time series by using the average as aggregation fun
R> myYearlyTS <- YEARLY(myMonthlyTS,'AVE')
R> #convert to daily by using central interpolation as disaggregation fun
R> myDailyTS <- DAILY(myMonthlyTS,'INTERP_CENTER')
```
Time Series Manipulation

The **bimets** package provides, among others, the following time series manipulation capabilities:

- Time series extension **TSEXTEND**
- Time series merging **TSMERGE**
- Time series projection **TSPROJECT**
- Lag **TSLAG**
- Lead **TSLEAD**
- Lag differences: standard, percentage, and logarithmic **TSDELTA TSDELTAP TSDELTALOG**
- Cumulative product **CUMPROD**
- Cumulative sum **CUMSUM**
- Moving average **MOVAVG**
- Moving sum **MOVSUM**
- Time series data presentation **TABIT**

Example:

```
R> # define two time series
R> myTS1 <- TIMESERIES(1:100,START=c(2000,1),FREQ='M')
R> myTS2 <- TIMESERIES(-(1:100),START=c(2005,1),FREQ='M')

R> # extend time series up to Apr 2020 with quadratic formula
R> myExtendedTS <- TSEXTEND(myTS1,UPTO = c(2020,4),EXTMODE = 'QUADRATIC')

R> # merge two time series with sum
R> myMergedTS <- TSMERGE(myExtendedTS,myTS2,fun = 'SUM')

R> # project time series on arbitrary time range
R> myProjectedTS <- TSPROJECT(myMergedTS,TSRANGE = c(2004,2,2006,4))

R> # lag and delta
R> myLagTS <- TSLAG(myProjectedTS,2)
R> myDeltaPTS <- TSDELTAP(myLagTS,2)

R> # moving average
R> myMovAveTS <- MOVAVG(myDeltaPTS,5)

R> # print data
R> TABIT(myMovAveTS,
R>> myTS1,
R>> TSRANGE=c(2004,8,2004,12)
```
bimets econometric modeling capabilities comprehend:

- Model Definition Language
- Estimation
- Simulation
- Multipliers Analysis
- Endogenous Targeting

We will go through each item of the list with a simple Klein model example (ref: "Economic Fluctuations in the United States" by L. R. Klein, Wiley and Sons Inc., New York, 1950).

**Model Definition Language**

bimets provides a language to unambiguously specify an econometric model. This section describes how to create a model and its general structure. The specification of an econometric model is translated and identified by keyword statements which are grouped in a model file, i.e. a plain text file with a specific syntax. Collectively, these keyword statements constitute the bimets Model Description Language (from now on MDL). The model specifications consist of groups of statements. Each statement begins with a keyword. The keyword classifies the component of the model which is being specified.

Below is an example of Klein’s model, that can either be stored in an R variable of class character or in a plain text file with a MDL compliant syntax.

The content of the *klein1.txt* variable is:

```r
R> klein1.txt <- "
MODEL
COMMENT> Consumption
BEHAVIORAL> cn
TSRANGE 1921 1 1941 1
EQ> cn = a1 + a2*p + a3*TSLAG(p,1) + a4*(w1+w2)
COEFF> a1 a2 a3 a4"
```

```
COMMENT> Investment
BEHAVIORAL> i
TSRANGE 1921 1 1941 1
EQ> i = b1 + b2*p + b3*TSLAG(p,1) + b4*TSLAG(k,1)
COEFF> b1 b2 b3 b4

COMMENT> Demand for Labor
BEHAVIORAL> w1
TSRANGE 1921 1 1941 1
EQ> w1 = c1 + c2*(y+t-w2) + c3*TSLAG(y+t-w2,1)+c4*time
COEFF> c1 c2 c3 c4

COMMENT> Gross National Product
IDENTITY> y
EQ> y = cn + i + g + t

COMMENT> Profits
IDENTITY> p
EQ> p = y - (w1+w2)

COMMENT> Capital Stock
IDENTITY> k
EQ> k = TSLAG(k,1) + i

END

Please note that there are circular dependencies between equations of the model, i.e. cn <-w1 <-y <-cn. Circular dependencies imply that the model simulation must be solved with an iterative algorithm.

As shown, the model definition is quite intuitive. The first keyword is MODEL, while at the end of the model definition we can find the END keyword. Available tags in the definition of a generic bimets model are:
- EQUATION> or BEHAVIORAL> indicate the beginning of a series of keyword statements describing a behavioral equation;
- IDENTITY> indicates the beginning of a series of keyword statements describing an identity or technical equation;
- EQ> specifies the mathematical expression for a behavioral equation or an identity equation;
- COEFF> specifies the coefficient names used in the EQ> keyword statement of a behavioral equation;
- ERROR> specifies an autoregressive process of a given order for the regression error;
- PDL> defines an Almon polynomial distributed lag;
- **RESTRICT** is a keyword that can be used to specify linear coefficient restrictions;

- **IF** is used to conditionally evaluate an identity during a simulation, depending on the value of a logical expression. Thus, it is possible to have a model alternating between two or more identity specifications for each simulation period, depending upon results from other equations;

- **IV** specifies the mathematical expression for an instrumental variable used in a behavioral equation;

- **COMMENT** can be used to insert comments into a model;

The mathematical expression in the EQ and IF definitions can include the standard arithmetic operators, parentheses, and the following MDL time series functions:

- **TSLAG(ts,i)**: lag the ts time series by i-periods;

- **TSDELTA(ts,i)**: i-periods difference of the ts time series;

- **TSDELTAP(ts,i)**: i-periods percentage difference of the ts time series;

- **TSDELTALOG(ts,i)**: i-periods logarithmic difference of the ts time series;

- **MOVAVG(ts,i)**: i-periods moving average of the ts time series;

- **MOVSUM(ts,i)**: i-periods moving sum of the ts time series;

- **LOG(ts)**: log of the ts time series;

- **EXP(ts)**: exponential of the ts time series;

- **ABS(ts)**: absolute values of the ts time series;

More details are available in MDL and LOAD_MODEL help pages. LOAD_MODEL() is the bimets function that reads an MDL model file and creates an equivalent R data structure.

Back to Klein's model example, the bimets LOAD_MODEL function reads the klein1.txt model as previously defined:

```r
R> kleinModel <- LOAD_MODEL(modelText = klein1.txt)
```

Analyzing behavioral...
Analyzing identities...
Optimizing...
Loaded model "klein1.txt":
  3 behavioral
  3 identities
  12 coefficients
...LOAD MODEL OK
As shown in the output, `bimets` counted 3 behavioral equations, 3 identities and 12 coefficients. Now in the R session there is a variable named `kleinModel` that contains the model structure defined in the `klein1.txt` variable. From now on, the user can ask `bimets` about any details of this model.

For example, to gather information on the "cn" Consumption behavioral equation:

```R
R> kleinModel$behaviorals$cn

$eq
[1] "cn=a1+a2*p+a3*TSLAG(p,1)+a4*(w1+w2)"

$eqCoefficientsNames
[1] "a1" "a2" "a3" "a4"

$eqComponentsNames
[1] "cn" "p" "w1" "w2"

$tsrange
[1] 1921 1 1941 1

$eqRegressorsNames
[1] "1" "p" "TSLAG(p,1)" "(w1+w2)"

$eqExp
expression(cn[2, ] = cn__ADDFACTOR[2, ] + +cn__a1 * 1 + cn__a2 * p[2, ] + cn__a3 * (p[1, ]) + cn__a4 * (w1[2, ] + w2[2, ]))

etc...

Users can always read (or carefully change) any model parameters. The `LOAD_MODEL` function parses behavioral and identity expressions of the MDL definition, but it also does an important optimization. Properly reordering the model equations is a key preparatory step in the later phase of the simulation, in order to guarantee performance and convergence, if any, with the aim of minimizing the number of feedback endogenous variables.

The `LOAD_MODEL` function builds the incidence matrix of the model, and uses this matrix to calculate the proper evaluation order of the model equations during the simulation.

Back to the Klein’s model example, the incidence matrix and the reordering of the equations are stored in the following variables:

```R
R> kleinModel$incidence_matrix

   cn i w1 y p k
  cn 0 0 1 0 1 0
  i  0 0 0 1 0 0
  w1 0 0 0 1 0 0
  y  1 1 0 0 0 0
  p  0 0 1 1 0 0
```
k 0 1 0 0 0
R> kleinModel$vpre
NULL
R> kleinModel$vsim
[1] "w1" "p" "cn" "i" "y"
R> kleinModel$vfeed
[1] "y"
R> kleinModel$vpost
[1] "k"

While simulating the Klein’s model, **bimets** will iterate on the computation of, in order, w1 -> p -> cn -> i -> y (the vsim variables), by looking for convergence on y (the vfeed variable, only one in this example) that is the feedback variable. If the convergence is achieved, it will calculate k (the vpost variable). The vpre array in this example is empty, that is no equation has to be evaluated before the iterative algorithm.

More details on the equations reordering are available in **MDL** and **LOAD_MODEL** help pages.

Once the model has been parsed, users needs to load the data of all the time series involved in the model, by using the **LOAD_MODEL_DATA** function. In the following example, the code defines a list of time series and loads this list into the Klein’s model previously defined:

R> kleinModelData <- list(
  cn = TIMESERIES(39.8,41.9,45.2,50.6,52.6,55.1,56.2,57.3,57.8,  
  55,50.9,45.6,46.5,48.7,51.3,57.7,58.7,57.5,61.6,65,69.7,  
  START=c(1920,1),FREQ=1),
  g = TIMESERIES(4.6,6.6,6.1,5.7,6.6,6.5,6.6,6.7,7,9.1,9.4,10.7,  
  10.2,9.3,10,10.5,10.3,11,13,14.4,15.4,22.3,  
  START=c(1920,1),FREQ=1),
  i = TIMESERIES(2.7,-.2,1.9,5.2,3.5,1.5,6.4,2.3,3.1,1,-3.4,-6.2,

START=c(1920,1), FREQ=1),

\( y = \text{TIMESERIES}(43.7, 40.6, 49.1, 55.4, 56.4, 58.7, 60.3, 61.3, 64, 67, 57.7,
50.7, 41.3, 45.3, 48.9, 53.3, 61.8, 65, 61.2, 68.4, 74.1, 85.3,
\text{START}=c(1920,1), \text{FREQ}=1),
\)

\( t = \text{TIMESERIES}(3.4, 7.7, 3.9, 4.7, 3.8, 5.7, 6.7, 4.2, 4.7, 7.1, 5.8, 3.5, 5.4,
6.8, 7.2, 8.3, 6.7, 7.4, 8.9, 9.6, 11.6,
\text{START}=c(1920,1), \text{FREQ}=1),
\)

\( \text{time} = \text{TIMESERIES}(\text{NA}, -10, -9, -8, -7, -6, -5, -4, -3, -2, -1, 0,
1, 2, 3, 4, 5, 6, 7, 8, 9, 10,
\text{START}=c(1920,1), \text{FREQ}=1),
\)

\( w2 = \text{TIMESERIES}(2.2, 2.7, 2.9, 2.9, 3.1, 3.2, 3.3, 3.6, 3.7, 4, 4.2, 4.8,
5.3, 5.6, 6, 6.1, 7.4, 6.7, 7.7, 8, 8.1, 8.5,
\text{START}=c(1920,1), \text{FREQ}=1)
\)

\)

\( \text{R} \> \text{kleinModel} \leftarrow \text{LOAD\_MODEL\_DATA(kleinModel, kleinModelData)} \)

Since time series and other data (e.g. regressor coefficients, error coefficients, constant adjustments, targets, instruments, etc...) are stored into the model object, users can define multiple model objects - each with its own arbitrary data - in the same \text{R} session. \text{bimets} makes it possible to estimate, simulate and compare results from different models with different data sets. Furthermore, users can easily save an estimated or a simulated model as a standard \text{R} variable, thus reloading it later, having all available data and time series stored into it, i.e. endogenous and exogenous time series, estimated coefficients, constant adjustments, simulation options, simulated time series, calculated instruments, targets, etc. (see also \text{RENORM} and \text{SIMULATE})

An advanced MDL model example follows:

\( \text{R} \> \text{#KLEIN MODEL WITH AUTOCORRELATION, RESTRICTIONS,}
\text{R} \> \text{#CONDITIONAL EVALUATIONS AND LHS FUNCTIONS}
\)

\( \text{R} \> \text{lhsKlein1.txt} \leftarrow " 
\)

\( \text{MODEL}
\)

\( \text{COMMENT} > \text{Modified Klein Model 1 of the U.S. Economy with PDL,}
\text{COMMENT} > \text{autocorrelation on errors, restrictions,}
\text{COMMENT} > \text{conditional evaluations and LHS functions on EQ}
\)

\( \text{COMMENT} > \text{Exp Consumption}
\text{BEHAVIORAL} > \text{cn}
\text{TSRANGE} 1925 1 1941 1
\text{EQ} > \text{EXP(cn) = a1 + a2*p + a3*TSLAG(p,1) + a4*(w1+w2)}
\text{COEFF} a1 a2 a3 a4
\text{ERROR} > AUTO(2)
\)

\( \text{COMMENT} > \text{Log Investment}
\text{BEHAVIORAL} > i \)
TSRANGE 1925 1 1941 1
EQ> LOG(i) = b1 + b2*p + b3*TSLAG(p,1) + b4*TSLAG(k,1)
COEFF> b1 b2 b3 b4
RESTRICT> b2 + b3 = 1

COMMENT> Demand for Labor
BEHAVIORAL> w1
TSRANGE 1925 1 1941 1
EQ> w1 = c1 + c2*(TSDELTA(y)+t-w2) + c3*TSLAG(TSDELTA(y)+t-w2,1)+c4*time
COEFF> c1 c2 c3 c4
PDL> c3 1 3

IF> LOG(i) > 0
IDENTITY> k
EQ> k = TSLAG(k,1)
IF> LOG(i) <= 0

END"

See MDL help page for details.

Estimation

The bimets ESTIMATE function estimates equations that are linear in the coefficients, as specified in the behavioral equations of the model object. Coefficients can be estimated for single equations or blocks of simultaneous equations. The estimation function supports:

- Ordinary Least Squares;
- Instrumental Variables;
- Deterministic linear restrictions on the coefficients;
- Almon Polynomial Distributed Lags;
- Autocorrelation of the errors;
- Structural stability analysis (Chow tests);

Restrictions procedure derives from the theory of Lagrange Multipliers, while the Cochrane-Orcutt method allows to account for residuals autocorrelation.
The estimation of the previously defined Klein's model is shown in the following example:

```r
R> kleinModel <- ESTIMATE(kleinModel)
```

Users can also estimate a selection of behavioral equations:

```r
R> kleinModel <- ESTIMATE(kleinModel, eqList=c('cn'))
```

```
.CHECK_MODEL_DATA(): warning, there are undefined values in time series "time".
```

Estimate the Model klein1.txt:
the number of behavioral equations to be estimated is 1.
The total number of coefficients is 4.

```

...ESTIMATE OK

Structural Stability

One of the main purposes of the econometric modeling is its use for forecast and policy evaluation and, to this end, the stability of a behavioral equation parameters over time should be verified. In order to check for structural stability two different procedures, which can be derived from the so called Chow-tests, are applied.

Given a sample of observations (i.e. the base TSRANGE) and selecting an arbitrary forward extension (i.e. the extended TSRANGE) we can perform the same regression by using these two time ranges.

In general a stability analysis is carried on in the following ways:
- comparing the parameter estimates arising from the two regressions: this is known as the covariance analysis;
- checking the accuracy of the forecast for the dependent variable in the extended TSRANGE, using the estimates produced in the base TSRANGE: this is known as the predictive power test.
The test statistic follows the $F$ distribution and can be performed during the `ESTIMATE()` function execution by using the `CHOWTEST` argument set to `TRUE` (more details in the `ESTIMATE` help page).

Example:

```r
#chow test for the consumption equation
#base TSRANGE set to 1921/1935
R> kleinModelChow <- ESTIMATE(kleinModel,
,eqList='cn'
,TSRANGE=c(1921,1,1935,1)
,forceTSRANGE=TRUE
,CHOWTEST=TRUE)
```

Estimate the Model klein1.txt:
The number of behavioral equations to be estimated is 1.
The total number of coefficients is 4.

Simulation

The simulation of an econometric model basically consists in solving the system of the equations describing the model for each time period in the specified time interval. Since the equations may also not be linear in the variables, and since the graph derived from the incidence matrix may be cyclic, the usual methods based on linear algebra are not applicable, and the simulation must be solved by using an iterative algorithm.

**bimets** simulation capabilities support:

- **Static simulations**: a static multiple equation simulation, in which the historical values for the lagged endogenous variables are used in the solutions of subsequent periods;

- **Dynamic simulations**: a dynamic simulation, in which the simulated values for the lagged endogenous variables are used in the solutions of subsequent periods;

- **Forecast simulations**: similar to dynamic simulation, but during the initialization of the iterative algorithm the starting values of endogenous variables in a period are set equal to the simulated values of the previous period. This allows the simulation of future endogenous observations, i.e.
the forecast;

- **Residuals check**: a single period, single equation simulation; simulated time series in output are just the computation of the RHS (right-hand-side) of their equation, by using the historical values of the involved time series and by accounting for error autocorrelation and PDLs, if any;

- **Partial or total exogenization of endogenous variables**: in the provided time interval (i.e. partial exog.) or in the whole simulation time range (i.e. total exog.), the values of the selected endogenous variables can be definitely set to their historical values, by excluding their equations from the iterative algorithm of simulation;

- **Constant adjustment of endogenous variables (add-factors)**: adds another exogenous time series - the "constant adjustment" - in the equation of the selected endogenous variables;

- **Backfill of simulated time series**: specifies the periods of historical data prior to the simulation time interval which are to be included in the simulation results;

More details are available in the SIMULATE help page.

Back to Kelin's model example, let's forecast the GNP (i.e. the "y" endogenous variable, originally referred as "Net national income, measured in billions of 1934 dollars", pag. 141 in "Economic Fluctuations in the United States" by L. R. Klein, Wiley and Sons Inc., New York, 1950) up to 1943:

R> #FORECAST GNP in 1942 and 1943

R> #we need to extend exogenous variables in 1942 and 1943
R> kleinModel$modelData <- within(kleinModel$modelData,
   
   w2 = TSEXTEND(w2, UPTO=c(1943,1))
   t = TSEXTEND(t, UPTO=c(1943,1))
   g = TSEXTEND(g, UPTO=c(1943,1))
   time = TSEXTEND(time, UPTO=c(1943,1),
   
   ,EXTMODE='LINEAR')

))

R> #simulate model
R> kleinModel <- SIMULATE(kleinModel
   ,simType='FORECAST'
   ,TSRANGE=c(1940,1,1943,1)
   ,simConvergence=0.00001
   ,simIterLimit=100
   )

Simulation: 100.00
...SIMULATE OK

R> #get forecasted GNP
In the following figure you will find the historical consumption, the dynamic simulated consumption and the RHS computation of the consumption equation, from 1921 to 1941:

Below is an example of advanced simulation:

```r
#STATIC SIMULATION EXAMPLE WITH EXOGENIZATION AND CONSTANT ADJUSTMENTS

#define exogenization list
#'cn' exogenized in 1923-1925
#'i' exogenized in the whole TSRANGE
exogenizeList <- list(
  cn = c(1923,1,1925,1),
  i = TRUE
)
```

R> #STATIC SIMULATION EXAMPLE WITH EXOGENIZATION AND CONSTANT ADJUSTMENTS

R> define exogenization list
R> #'cn' exogenized in 1923-1925
R> #'i' exogenized in the whole TSRANGE
R> exogenizeList <- list(
  cn = c(1923,1,1925,1),
  i = TRUE
)
Multipliers Analysis

The `bimets` `MULTMATRIX` function computes the matrix of both impact and interim multipliers, for a selected set of endogenous variables (i.e. `TARGET`) with respect to a selected set of exogenous variables (i.e. `INSTRUMENT`), by subtracting the results from different simulations in each period of the provided time range (i.e. `TSRANGE`). The simulation algorithms are the same as those used for the `SIMULATE` operation.

The `MULTMATRIX()` procedure is articulated as follows:

1. simultaneous simulations are done;
2. the first simulation establishes the base line solution (without shocks);
3. the other simulations are done with shocks applied to each of the `INSTRUMENT` one at a time for every period in `TSRANGE`;
4. each simulation follows the defaults described in the Simulation section, but has to be `STATIC` for the IMPACT multipliers and `DYNAMIC` for INTERIM multipliers;
5. given the `MM_SHOCK` shock amount as a very small positive number, derivatives are computed by subtracting the base line solution of the `TARGET` from the shocked solution, then dividing by the value of the base line `INSTRUMENT` times the `MM_SHOCK`;

`bimets` users can also declare an endogenous variable as the `INSTRUMENT` variable. In this case, the constant adjustment related to the provided endogenous variable will be used as the `INSTRUMENT` exogenous variable.

Back to our Klein’s model example, we can calculate impact multipliers of Government non-Wage Spending ”g” and Government Wage Bill ”w2” with respect of Consumption ”cn” and Gross National Product ”y” in the year 1941 by using the previously estimated model:
R> kleinModel <- MULTMATRIX(kleinModel, 
  TSRANGE=c(1941,1,1941,1), 
  INSTRUMENT=c('w2','g'), 
  TARGET=c('cn','y'))

Multiplier Matrix: 100.00
...MULTMATRIX OK

R> kleinModel$MultiplierMatrix

                   w2_1  g_1
     cn_1  0.4540346 1.671956
     y_1   0.2532000 3.653260

Results show that the impact multiplier of "y" with respect to "g" is +3.65. If we change the Government non-Wage Spending "g" value in 1941 from 22.3 (his historical value) to 23.3 (+1), then the simulated Gross National Product "y" in 1941 changes from 95.2 to 99, thusly roughly confirming the +3.65 impact multiplier. Note that "g" only appears once in the model definition, and only in the "y" equation, with a coefficient of one (Keynes would approve).

An interim-multiplier example follows:

R> #multi-period interim multipliers
R> kleinModel <- MULTMATRIX(kleinModel, 
  TSRANGE=c(1940,1,1941,1), 
  INSTRUMENT=c('w2','g'), 
  TARGET=c('cn','y'))

Multiplier Matrix: 100.00
...MULTMATRIX OK

R> #output multipliers matrix (note the zeros where the period
R> #of the INSTRUMENT is greater than the period of the TARGET)
R> kleinModel$MultiplierMatrix

                   w2_1  g_1  w2_2  g_2
     cn_1  0.4478202 1.582292 0.0000000 0.000000
     y_1   0.2433382 3.510971 0.0000000 0.000000
     cn_2 -0.3911001 1.785042 0.4540346 1.671956
     y_2  -0.6251177 2.843960 0.2532000 3.653260

**Endogenous Targeting**

The endogenous targeting of econometric models consists of solving the model while interchanging the role of one or more endogenous variables with an equal number of exogenous variables.

The bimets *RENORM* procedure determines the values for the INSTRUMENT exogenous variables which allow the objective TARGET endogenous variables to be achieved, with respect to the constraints given by the model MDL definition.
This is an approach to economic and monetary policy analysis, and is based on two assumptions:

1. there exists a desired level for a set of \( n \) endogenous variables of the model defined as \( \text{TARGET} \);
2. there exists a set of \( n \) exogenous variables defined as \( \text{INSTRUMENT} \);

Given these premises, the endogenous targeting process consists in determining the values of the exogenous variables chosen as \( \text{INSTRUMENT} \) allowing us to achieve the desired values for the endogenous variables designated as \( \text{TARGET} \). In other words the procedure allows users to exchange the role of exogenous and endogenous among a set of variables pairs.

Given a list of exogenous \( \text{INSTRUMENT} \) variables and a list of \( \text{TARGET} \) endogenous time series, the iterative procedure can be split into the following steps:

1. Computation of the multipliers matrix \( \text{MULTMAT} \) of the \( \text{TARGET} \) endogenous variables with respect to the \( \text{INSTRUMENT} \) exogenous variables (this is a square matrix by construction);

2. Solution of the linear system (if any):
\[
V_{\text{exog}}(i + 1) = V_{\text{exog}}(i) + \text{MULTMAT}^{-1} \ast (V_{\text{endog}}(i) - \text{TARGET}),
\]
where \( V_{\text{exog}}(i) \) are the exogenous variables in the \( \text{INSTRUMENT} \) list and \( V_{\text{endog}}(i) \) are the endogenous variables that have a related target in the \( \text{TARGET} \) list, given \( i \) the current iteration;

3. Simulation of the model with the new set of exogenous variables computed in step 2, then a convergence check by comparing the subset of endogenous variables arising from this simulation and the related time series in \( \text{TARGET} \) list. If the convergence condition is satisfied, or the maximum number of iterations is reached, the algorithm will stop, otherwise it will go back to step 1;

Users can also declare an endogenous variable as an \( \text{INSTRUMENT} \) variable. In this case, the constant adjustment related to the provided endogenous variable will be used as the instrument exogenous variable. This procedure is particularly suited for the automatic computation of the add-factors needed to fine tune the model into a baseline path and to improve the forecasting accuracy.

If the convergence condition is satisfied, the \( \text{RENORM} \) procedure will return the requested \( \text{INSTRUMENT} \) time series allowing to achieve the desired values for endogenous variables designated as \( \text{TARGET} \).

Back to our Klein's model example, we can perform the endogenous targeting of the previously estimated model. First of all, the targets must be defined:

\`
#we want an arbitrary value on Consumption of 66 in 1940 and 78 in 1941
#we want an arbitrary value on GNP of 77 in 1940 and 98 in 1941

kleinTargets <- list(
  cn = TIMESERIES(66,78,START=c(1940,1),FREQ=1),
  y = TIMESERIES(77,98,START=c(1940,1),FREQ=1)
)
```

Then, we can perform the model endogenous targeting by using the "w2" (Wage Bill of the Government Sector) and the "g" (Government non-Wage Spending) exogenous variables as \( \text{INSTRUMENT} \),
in the years 1940 and 1941:

R> kleinModel <- RENORM(kleinModel
   ,INSTRUMENT = c('w2', 'g')
   ,TARGET = kleinTargets
   ,TSRANGE = c(1940,1,1941,1)
   ,simIterLimit = 100
)

Once RENORM completes, the calculated values of exogenous INSTRUMENT allowing us to achieve the desired endogenous TARGET values are stored into the model:

R> with(kleinModel, TABIT(modelData$w2,
    renorm$INSTRUMENT$w2,
    modelData$g,
    renorm$INSTRUMENT$g,
    TSRANGE=c(1940,1,1941,1)
)

DATE, PER, modelData$w2, renorm$INSTRUMENT$w2, modelData$g, renorm$INSTRUMENT$g
1940, 1, 8, 7.413331, 15.4, 16.1069
1941, 1, 8.5, 9.3436, 22.3, 22.65985

So, if we want to achieve on "cn" (Consumption) an arbitrary simulated value of 66 in 1940 and 78 in 1941, and if we want to achieve on "y" (GNP) an arbitrary simulated value of 77 in 1940 and 98 in 1941, we need to change exogenous "w2" (Wage Bill of the Government Sector) from 8 to 7.41 in 1940 and from 8.5 to 9.34 in 1941, and we need to change exogenous "g" (Government non-Wage Spending) from 15.4 to 16.1 in 1940 and from 22.3 to 22.66 in 1941.

Let's verify:

R> #create a new model
R> kleinRenorm <- kleinModel

R> #get instruments to be used
R> newInstruments <- kleinModel$renorm$INSTRUMENT

R> #change exogenous by using new instruments data
R> kleinRenorm$modelData <- within(kleinRenorm$modelData,
   {
      w2[[1940,1]] = newInstruments$w2[[1940,1]]
      w2[[1941,1]] = newInstruments$w2[[1941,1]]
      g[[1940,1]] = newInstruments$g[[1940,1]]
      g[[1941,1]] = newInstruments$g[[1941,1]]
   }
)

R> #users can also replace last two commands with:
R> #kleinRenorm$modelData <- kleinRenorm$renorm$modelData

R> #simulate the new model
R> kleinRenorm <- SIMULATE(kleinRenorm,
      TSRANGE=c(1940,1,1941,1),
      simConvergence=0.00001,
      simIterLimit=100
  )

Simulation: 100.00
...SIMULATE OK

R> #verify targets are achieved
R> with(kleinRenorm$simulation,
      TABIT(cn,y)
  )

DATE, PER, cn , y
1940, 1 , 66.01116 , 77.01772
1941, 1 , 78.02538 , 98.04121

**bimets** estimation and simulation results have been compared to the output results of leading commercial econometric software, by using several large and complex models.

The models used in the comparison have more than:

+100 behavioral equations;
+700 technical identities;
+500 coefficients;
+1000 time series of endogenous and exogenous variables;

In these models we can find equations with restricted coefficients, polynomial distributed lags, error autocorrelation and conditional evaluation of technical identities; all models have been simulated in static, dynamic, and forecast mode, with exogenization and constant adjustments of endogenous variables through the use of **bimets** capabilities.

In the +800 endogenous simulated time series over the +20 simulated periods (i.e. more than 16,000 simulated observations), the average percentage difference between **bimets** and leading commercial software results has a magnitude of $10^{-7}$. The difference between results calculated by using different commercial software has the same average magnitude.

**bimets** stands for Bank of Italy Model Easy Time Series; it does not depend on compilers or third-party software so it can be freely downloaded and installed on Linux, MS Windows(R) and Mac OSX(R), without any further requirements.

Description

This function returns the array built with input argument values. Input can be time series, numerical arrays or strings.

Usage

A1D(..., length = NULL, avoidCompliance = FALSE)
Arguments

... 
Input argument list. This function accepts strings, time series, objects of class numeric or logical. Input time series must satisfy the compliance control check defined in `is.bimets`

length 
Length of output array, that must be greater than the sum of each input argument size: if the length of the output array is provided, than the output array will be eventually filled with zeros.

avoidCompliance 
If TRUE, compliance control check of input time series will be skipped. See `is.bimets`

Value

This function returns an array of the same class of the input.

See Also

`NOELS`
`is.bimets`

`TIMESERIES`
`TSDATES`
`LOCS`
`NAMELIST`
`INTS`
`TSINFO`
`TSLOOK`
`TABIT`
`ELIMELS`
`INDEXNUM`

Examples

```r
n=10;
#create ts
ts1=TSERIES(rnorm(n),START=c(2000,1),FREQ=1)

#create A1D() array with scalars, ts, and NA
out_a1d=A1D(length=25, ts1, 1, -8.9, NA)
print(out_a1d)

#same example no length specified
out_a1d=A1D(ts1, 1, -8.9, NA)
print(out_a1d)

#strings example
out_a1d=A1D(length=5,'aa','bb','ccc')
print(out_a1d)
```
**Annual Time Series (Dis)Aggregation**

**Description**

This function returns a yearly aggregated time series, by using as input a semiannual, quarterly, monthly or daily time series.

**Usage**

```r
ANNUAL(x = NULL, fun = NULL, avoidCompliance = FALSE, ...)
YEARLY(x = NULL, fun = NULL, avoidCompliance = FALSE, ...)
```

**Arguments**

- `x` Input time series, that must satisfy the compliance control check defined in `is.bimets`.
- `fun`
  - `STOCK`: the output value of a year is equal to the value of the input time series in the last period of the same year
  - `NSTOCK`: the output value of a year is equal to the value of the input time series in the last non-missing NA period of the same year
  - `SUM`: the output value of a year is equal to the sum of all the observations of the input time series in the same year
  - `NSUM`: the output value of a year is equal to the sum of all the non-missing NA observations of the input time series in the same year
  - `AVE`: the output value of a year is equal to the average of all the observations of the input time series in the same year
  - `NAVE`: the output value of a year is equal to the average of all the non-missing NA observations of the input time series in the same year
- `avoidCompliance` If TRUE, compliance control check of input time series will be skipped. See `is.bimets`
- `...` Backward compatibility.

**Value**

This function returns a yearly BIMETS time series.

**See Also**

- `SEMIANNUAL`
- `QUARTERLY`
- `MONTHLY`
- `DAILY`
Examples

```r
# TS DAILY TO ANNUAL
n=366
ts1=TIMESERIES(0:n,START=c(2000,1),FREQ='D')
ts1[10]=NA
TABIT(ANNUAL(ts1,fun='NAVE'))

# TS DAILY TO ANNUAL
n=36
ts1=TIMESERIES(0:n,START=c(2000,1),FREQ='M')
ts1[10]=NA
TABIT(YEARLY(ts1,fun='SUM'))
```

as.bimet Convert a Time Series to BIMETS

Description

This function tries to convert a time series of class ts() or xts() into a BIMETS time series that satisfy the compliance control check defined in is.bimets

All the information in the input time series will be preserved.

Input time series must be of class ts() or xts(), and will be converted in the BIMETS class-type specified in the global option BIMETS_CONF_CCT (see BIMETS configuration).

If the input time series has a temporal discontinuity (i.e. a missing pair Date-Value in the case of xts() time series) then the missing pair Date-Value is inserted in the output time series with a missing value NA, or with the value provided in the FILLVALUE argument.

If BIMETS_CONF_CCT='XTS', in the case of a monthly time series the .indexCLASS is converted to the class yearmon(); in the case of a quarterly time series the .indexCLASS is converted to yearqtr(); in the case of other input frequency the .indexCLASS is converted to Date(). If BIMETS_CONF_CCT='XTS' the dates of all the output observations are set accordingly to the BIMETS global option BIMETS_CONF_DIP, i.e. the first or the last dates in the period (see BIMETS configuration).

If the input time series has multiple observations in the same date, e.g. an xts() with a two or more observations in the same date, the duplication is removed and the output time series will contain only the later observation (see examples).

If the input time series is multivariate the output time series will contain only the first column of the input matrix of data (where the matrix of data is the matrix built with the aligned input time series as columns).

If the input time series is a daily time series of class xts() and the global option BIMETS_CONF_CCT='TS' then the 366 period of the output time series in each non-bisextile year will have the value of the 365 period in the same year (duplicated value).
usage

as.bimets(x=NULL, FILLVALUE=NA, VERBOSE=FALSE, ...)

Arguments

x                Input time series of class ts() or xts().
FILLVALUE        Value inserted in the output time series in the case of temporal discontinuity. Defaults to missing NA.
VERBOSE          If TRUE, a verbose description of inserted and/or removed observations, if any, will be shown.
...               Backward compatibility.

Value

This function returns a BIMETS time series (see also BIMETS configuration).

---

### BIMETS Global Options Configuration

**Description**

BIMETS package depends on some options in order to transform and to present time series data. These options can be read or changed by using the functions:

- `setBIMETSconf(opt,value)` and `getBIMETSconf(opt)`

**Usage**

- `setBIMETSconf(opt=NULL, value=NULL, suppressOutput=FALSE)`
- `getBIMETSconf(opt=NULL)`
Arguments

opt

Name of the BIMETS option. Available option names are:

**BIMETS_CONF_DIP**: Date In Period. Users can associate to each observation in a time series the first or the last date in the period, i.e. 1 January or 31 December in the case of an yearly time series, 1 January/1 July or 30 June/31 December in the case of a semiannual time series, 1 January/31 January in the case of a monthly time series in January, etc. The assignments by date to time series (e.g. `ts[’2000-01-01’]=value`) need to be coherent to the value of this global option. Accepted values are:

- **LAST**: (default) each observation has associated the last date of the period, e.g. 31 Mar for a quarterly time series, 31 January for a monthly time series in the first period, etc.
- **FIRST**: each observation has associated the first date of the period, e.g. 1 Jan for a quarterly time series, 1 Feb for a monthly time series in the second period, etc.

**BIMETS_CONF_CCT**: Constructor Class Type. The package supports `ts()` and `xts()` time series as input arguments; furthermore the user can select the base class of a BIMETS time series, i.e. the class used when a time series is created with `TIMESERIES()` or converted to BIMETS with `as.bimets()`. This is a global option; Users can locally override the selection of the output class by using the `class=’TS’` or `class=’XTS’` argument in the `TIMESERIES()` function. The option **BIMETS_CONF_CCT** can be assigned to the following values:

- **TS**: (default) the time series constructor `TIMESERIES()` and the conversion function `as.bimets()` return an object of class `ts()`
- **XTS**: the time series constructor `TIMESERIES()` and the conversion function `as.bimets()` return an object of class `xts()`.

Please note that BIMETS package performs better with **BIMETS_CONF_CCT=’TS’**

**BIMETS_CONF_NOC**: NO Compliance test. If this option is set **TRUE** then the compliance control check on input time series, i.e. `is.bimets()`, will be globally disabled. The default is set to **FALSE**. The compliance check on input time series should generally be active, otherwise a malformed input time series can produce unwanted results in operations.

value

The value to be assigned to the BIMETS option.

suppressOutput

If **TRUE**, the output messages will be disabled.

Value

This function set or read global BIMETS options, and return a NULL value.

See Also

- `TIMESERIES`
- `is.bimets`
Examples

```r
#default BIMETS_CONF_DIP is LAST
#create ts
ts1=TSERIES((1:10),START=c(2000,1),FREQ=1)

#transform to xts and print
xt1=fromBIMETStoXTS(ts1)
print(xt1)  #....dates as of 31 Dec

#set configuration BIMETS_CONF_DIP to FIRST
setBIMETSconf('BIMETS_CONF_DIP','FIRST')

#create ts
ts1=TSERIES((1:10),START=c(2000,1),FREQ=1)

#transform to xts and print
xt1=fromBIMETStoXTS(ts1)
print(xt1)  #....dates as of 1 Jan

#set configuration BIMETS_CONF_DIP to LAST
setBIMETSconf('BIMETS_CONF_DIP','LAST')

#work on XTS
setBIMETSconf('BIMETS_CONF_CCT','XTS')

#check compliance of xt1 and fail...
is.bimets(xt1)  #... FALSE

#set configuration BIMETS_CONF_DIP to FIRST
setBIMETSconf('BIMETS_CONF_DIP','FIRST')

#check compliance of xt1 and ok...
is.bimets(xt1)  #... TRUE

print(getBIMETSconf('BIMETS_CONF_DIP'))  # ... returns FIRST
print(getBIMETSconf('BIMETS_CONF_CCT'))  # ... returns XTS

print(is.xts(TSERIES(1:10,START=c(2000,1),FREQ=1)))  #...print TRUE
print(is.ts(TSERIES(1:10,START=c(2000,1),FREQ=1,class='TS')))  #...print TRUE

#NOC
setBIMETSconf('BIMETS_CONF_CCT','XTS')
```
is.bimets(xts()) #FALSE
setBIMETSconf('BIMETS_CONF_NOC',TRUE)
is.bimets(xts()) #TRUE

#...back to default
setBIMETSconf('BIMETS_CONF_DIP','LAST')
setBIMETSconf('BIMETS_CONF_CCT','TS')
setBIMETSconf('BIMETS_CONF_NOC',FALSE)

CUMPROD  

**Cumulative Product**

**Description**

This function returns the cumulative product of the elements of the input array or time series. The result is an object of the same class of the input, and its elements are the cumulative product of the current and the previous elements of the input.

If the input is a time series, users can provide the argument TS RANGE in order to project the input time series before the cumulative product.

**Usage**

CUMPROD(x=NULL, TS RANGE=NULL, avoidCompliance=FALSE, ...)
Arguments

x  
   Input numerical array or time series that must satisfy the compliance control check defined in \texttt{is.bimets}.

\texttt{TSRANGE}  
   Optional date range of operations that process the input time series. \texttt{TSRANGE} must be specified as an array composed by starting year, starting period, ending year and ending period, i.e. \texttt{TSRANGE=c(START\_Y,START\_P,END\_Y,END\_P)}. The projection into the time interval specified in \texttt{TSRANGE} takes place before the cumulative product.

\texttt{avoidCompliance}  
   If \texttt{TRUE}, compliance control check of input time series will be skipped. See \texttt{is.bimets} ...

...  
   Backward compatibility.

Value

This function returns an object of the same class of the input, i.e. an array or a BIMETS time series.

See Also

\texttt{TSPROJECT}
\texttt{MOVAVG}
\texttt{TSDELTA}
\texttt{TSLAG}
\texttt{TSPROJECT}
\texttt{TSEXTEND}
\texttt{TSLEAD}
\texttt{INDEXNUM}

Examples

```
# create ts
ts1=TSERIES(1:10,START=c(2000,1),FREQ='M')
out\_CUMPROD=CUMPROD(ts1)
TABIT(out\_CUMPROD)

out\_CUMPROD=CUMPROD(ts1,TSRANGE=c(2000,4,2001,1))
TABIT(ts1,out\_CUMPROD)

# define an array
arr1=c(1:5,-1:-5)
out\_CUMPROD=CUMPROD(arr1)
print(out\_CUMPROD)
```
Description

This function returns the cumulative sum of the elements of the input array or time series. The result is an object of the same class of the input, and its elements are the cumulative sum of the current and the previous elements of the input.

If the input is a time series, users can provide the argument TSRANGE in order to project the input time series before the cumulative sum.

CUMULO is an alias form CUMSUM with the argument MODE='YEARLY'.

Usage

\[
\text{CUMSUM}(x=\text{NULL}, \text{TSRANGE}=\text{NULL}, \text{MODE}=\text{NULL}, \text{avoidCompliance}=\text{FALSE}, ...)
\]

\[
\text{CUMULO}(x=\text{NULL}, \text{TSRANGE}=\text{NULL}, \text{avoidCompliance}=\text{FALSE}, ...)
\]

Arguments

- **x**: Input numerical array or time series that must satisfy the compliance control check defined in is.bimets.
- **TSRANGE**: Optional date range of operations that process time series. TSRANGE must be specified as an array composed by starting year, starting period, ending year and ending period, i.e. TSRANGE=c(START_YEAR,START_PERIOD,END_YEAR,END_PERIOD). The projection into the time interval specified in TSRANGE takes place before the cumulative sum.
- **MODE**: When selecting MODE='YEARLY' or MODE='MONTHLY' the sum is reset to zero when a new year or a new month starts.
- **avoidCompliance**: If TRUE, compliance control check of input time series will be skipped. See is.bimets

Value

This function returns an object of the same class of the input, i.e. an array or a BIMETS time series.

See Also

- TSPROJECT
- MOVAVG
- TSDELTA
- TSLAG
- TSPROJECT
- TSEXTEND
Examples

```r
# create ts
ts1 = TSERIES(INTS(1, 30), START = c(2000, 1), FREQ = 'M')
out_CUMSUM = CUMSUM(ts1)
TABIT(out_CUMSUM)

out_CUMSUM = CUMSUM(ts1, TSRANGE = c(2000, 4, 2001, 7))
out_CUMSUM_Y = CUMSUM(ts1, TSRANGE = c(2000, 4, 2001, 7), MODE = 'YEARLY')
TABIT(ts1, out_CUMSUM, out_CUMSUM_Y)

# define an array
arr1 = c(INTS(1, 10), INTS(-1, -10))
out_CUMSUM = CUMSUM(arr1)
print(out_CUMSUM)

# print... 1 3 6 10 15 21 ... 27 19 10 0
```

**DAILY**

*Daily Time Series (Dis)Aggregation*

**Description**

This function returns a daily disaggregated time series, by using as input an annual, semiannual, quarterly or monthly time series.

**Usage**

`DAILY(x = NULL, fun = NULL, avoidCompliance = FALSE, ...)`

**Arguments**

- **x**: Input time series, that must satisfy the compliance control check defined in `is.bimets`.
- **fun**: `NULL`: (default) the output value of each daily observation is set equal to the value of the input observation the date belongs to (i.e. duplicated values over the period)
  - `INTERP_END`: the value of the input time series in a period is copied into the
This function converts a Date() object to an array $c(\text{YEAR}, \text{PERIOD})$, where \text{YEAR} and \text{PERIOD} are the year-period the input Date() belongs to, given an input frequency.
**Arguments**

- **x**: Input of class `Date()`.
- **f**: Positive integer. Valid values are: 1, 2, 3, 4, 12, 24, 36, 53, 366

**Value**

This function returns a two-dimensional array `c(YEAR, PERIOD)`.

**See Also**

- `yq2yp`
- `ym2yp`
- `GETDATE`
- `INTS`
- `TABIT`

**Examples**

```r
print(date2yp(as.Date("2001/06/30"), 2)) # 2001,1
print(date2yp(as.Date("2002/03/23"), 1)) # 2002,1
print(date2yp(as.Date("2003/07/01"), 366)) # 2003,182
print(date2yp(as.Date("2004/09/13"), 2)) # 2004,2
print(date2yp(as.Date("2004/01/13"), 12)) # 2004,1
print(date2yp(as.Date("2004/07/24"), 4)) # 2004,3
print(date2yp(c(as.Date("1900-01-01"), as.Date("1944-12-01"),
               as.Date("1964-06-12"), as.Date("1923-03-01"),
               as.Date("1943-12-05"), f=366)) #...
```

---

**ELIMELS**

*Eliminate Elements from Arrays or Time Series*

**Description**

This function eliminates the selected elements from the input array or the input time series.

**Usage**

```r
ELIMELS(x=NULL, idx=NULL, avoidCompliance=FALSE, ...)
```

**Arguments**

- **x**: Input numerical array or time series that must satisfy the compliance control check defined in `is.bimets`. 
idx  Numerical array built with the indexes of selected elements to be removed from the input. If the input is a time series the index must be provided as a sequence of numbers \( \text{IDX} = \text{YEAR} + \text{PERIOD}/\text{FREQ} \) with \( \text{YEAR} \) and \( \text{PERIOD} \) the year and the period to be removed (see example).

avoidCompliance

If TRUE, compliance control check of input time series will be skipped. See \texttt{is.bimets}.

...  Backward compatibility.

Value

This function returns an array with the kept elements from the input array or the input time series.

# 2 3 6 7 8 9 10

print(ELIMELS(TSERIES(1:10,START=c(2000,1),FREQ=4),c(2000.25,2000.75)))
# 2 4 5 6 7 8 9 10
```

---

\emph{ESTIMATE}

\textit{Estimate a BIMETS model object}
Description

This function estimates equations that are linear in the coefficients, as specified in the behavioral equations of the input model object. Coefficients can be estimated for single equations or blocks of simultaneous equations. Coefficients restriction procedure derives from the theory of Lagrange Multipliers, while the Cochrane-Orcutt method allows to account for residuals autocorrelation.

The estimation function supports:

- Ordinary Least Squares;
- Instrumental Variables;
- Deterministic linear restrictions on the coefficients;
- Almon Polynomial Distributed Lags;
- Autocorrelation of the errors;
- Structural stability analysis (Chow tests);

Further details on estimation calculus can be found in MDL help page; further details on Chow test can be found below in this section;

Usage

ESTIMATE(model=NULL,
eqList=NULL,
TSRANGE=NULL,
forceTSRANGE=FALSE,
estTech='OLS',
IV=NULL,
forceIV=FALSE,
quietly=FALSE,
showWarnings=FALSE,
tol=.Machine$double.eps,
digits=getOption('digits'),
centerCOV=TRUE,
CHOWTEST=FALSE,
CHOWPAR=NULL,
avoidCompliance=FALSE,
...)

Arguments

model The BIMETS model object to be estimated (see also LOAD_MODEL).
eqList The character array of behavioral names to be estimated. If it is NULL then all the behaviorals of the model will be estimated.
TSRANGE The time range of the estimation, as a four dimensional numerical array, i.e. TSRANGE=c(start_year,start_period,end_year,end_period). The TSRANGE provided in the behavioral MDL definition takes precedence over this function argument.
forceTSRANGE  If TRUE, the TSRANGE defined in the previous argument takes precedence over the TSRANGE provided in the behavioral MDL definition.

estTech  The estimation technique used in the regression. Ordinary Least Squares OLS and Instrumental Variables estimation IV are supported.

IV  The character array built with the Instrumental Variable expressions, in the case of Instrumental Variables estimation (see examples).

forceIV  If TRUE, the IV defined in the previous argument takes precedence over the IV provided in the behavioral MDL definition.

quietly  If TRUE, information messages will be suppressed, e.g. results and regression statistics.

showWarnings  If TRUE and if a model time series has a missing value then warning message will be shown.

tol  The tolerance for detecting linear dependencies in the columns of a matrix while an inversion is requested. The default is .Machine$double.eps.

digits  Controls the number of digits to print when printing coefficients and statistics of the estimation. Valid values are 1 to 22 with a default of 7.

centerCOV  If TRUE, the function subtracts the mean from the residuals before calculating the residual covariance matrix.

CHOWTEST  If TRUE, the structural stability analysis will be performed.

CHOWPAR  Indicates the last year-period where the stability test is performed. If NULL it will be automatically calculated by using all available time series data. It must be provided as an integer array, e.g. c(YEAR, PERIOD).

avoidCompliance  If TRUE, compliance control check of model time series will be skipped. See is.bimets

...  Backward compatibility.

Value

If outputText=TRUE, for each behavioral in the eqList this function will print out:

- the name of the estimated behavioral;
- the estimation technique used;
- the autocorrelation order of the error, if any, and the iterations count required to achieve the convergence;
- the estimated equation with calculated coefficients and regressor expression; for each coefficient the T-statistic and the significance will be printed out;
- the restriction equations imposed on the coefficients, if any;
- the F-test for the restrictions, including the PDL restrictions, if any;
- the final autocorrelation parameters for the error, along with their standard error, the T-statistic and the significance;
- the R-Squared and the Adjusted R-Squared;
- the Durbin-Watson Statistic;
- the Sum of squares of residuals;
- the Standard Error of Regression;
- the Log of the Likelihood Function;
- the F-statistic and the F-probability;
- the AIC and the BIC;
- the Mean of the Dependent Variable;
- the Number of Observations;
- the Number of Degrees of Freedom;
- the Current Sample, i.e. the TSRANGE of estimation;

All probabilities lie between [0, 1].

For each behavioral in the eqList this function will add 4 new named elements into the related behavioral of the output model object:

1) coefficients: a numerical array built with the estimated coefficients;
2) errorCoefficients: a numerical array built with the estimated coefficient for the error autoregression, if the ERROR> structure has been provided in the model MDL definition;
3) residuals: the time series of the regression residuals. If an ERROR> structure has been provided in the behavioral definition, the related residuals will be calculated as described in the Cochrane-Orcutt procedure (see MDL).
3) residuals_no_error_correction: if an ERROR> structure has been provided in the behavioral definition, the residuals calculated by using the original dependent and independent variables are stored into this list element.
4) statistics: a list built with the parameters and the statistics of the estimation, e.g.:
   - TSRANGE: TSRANGE requested in the latest estimation of the behavioral;
   - estimationTechnique: estimation technique requested in the latest estimation of the behavioral;
   - CoeffCovariance: coefficients covariance;
   - StandardErrorRegression and StandardErrorRegressionNotCentered: standard error of the regression (centered and not-centered);
   - CoeffTstatistic: T-statistic of the coefficients;
   - RSquared: R-Squared;
   - AdjustedRSquared: adjusted R-Squared;
   - DegreesOfFreedom: degrees of freedom of the regression;
   - CoeffPvalues: coefficients p-values;
   - LogLikelihood: Log of the Likelihood Function;
   - Fstatistics: F-statistics;
   - RhosTstatistics: rhos T-statistic (if any);
   - FtestRestrValue: F-test value for the restrictions;
   - FtestRestrProbability: F-test probability for the restrictions;
   - AIC: Akaike’s Information Criterion;
   - BIC: Schwarz’s Information Criterion;
   - matrixX: the regressors matrix;
   - vectorY: the dependent variable;
   - matrixX_error_corrected: the regressors matrix arising from the Cochrane-Orcutt procedure;
   - etc.

*Structural Stability - Chow test*
One of the main purposes of the econometric modeling is its use for forecast and policy evaluation and, to this end, the stability of a behavioral equation parameters over time should be verified. In order to check for structural stability two different procedures, which can be derived from the so-called Chow-tests, are applied.

Given a sample of $T_0 = t_k, ..., t_n$ observations (i.e. the base TSRANGE) and selecting an arbitrary forward extension in $T_1 = t_k, ..., t_n, ..., t_m$ observations (i.e. the extended TSRANGE) in the general case we have the following two regressions:

1) $Y_0 = \beta_0 \ast X_0 + \epsilon_0$, $\epsilon_0 \sim N(0, \sigma_0^2)$, having time series projected on the base TSRANGE
2) $Y_1 = \beta_1 \ast X_1 + \epsilon_1$, $\epsilon_1 \sim N(0, \sigma_1^2)$, having time series projected on the extended TSRANGE

In general a stability analysis is carried on in the following ways:
- comparing the parameter estimates arising from the two regressions: this is known as the covariance analysis;
- checking the accuracy of the forecast for the dependent variable in the extended TSRANGE, using the estimates produced in the base TSRANGE: this is known as the predictive power test.

The first Chow test is calculated as:

$$\tau = \frac{SSR_1 - SSR_0}{SSR_0 \ast \frac{DoF_1 - DoF_0}{DoF_1}}$$

with $SSR_i$ as the sum of squared residuals and $DoF_i$ as the number of degrees of freedom in the regression $i = 0, 1$.

The test is completed by calculating the following time series on the extended TSRANGE:
- the forecast error;
- the standard error of forecast;
- the t-statistic for the error;

The standard error of the forecast for the $t_j$ observation in the extended TSRANGE is computed according to:

$$SE_j = \sigma_0 \sqrt{1 + x_j^\top * (X_0^\top \ast X_0)^{-1} * x_j}$$

having $x_j$ as the independent values (i.e. regressors) on the $t_j$ observation in the $T_1$ extended TSRANGE, with $n < j \leq m$.

The null hypothesis for $\tau$ is:

$$H^*: \beta_1 = \beta_0, \text{ given } \sigma_1^2 = \sigma_0^2$$

The test statistic $\tau$ follows the $F$ distribution with $(DoF_1 - DoF_0)$ and $DoF_1$ degrees of freedom, and can be performed during the \textsc{Estimate()} function execution by using the \textsc{ChowTest} argument set to \textsc{TRUE}.

If \textsc{ChowTest} is \textsc{TRUE}, for each behavioral in the eqList the output model will have the following named element:
- \textsc{ChowTest}: it contains the statistics and the time series computed during the last structural analysis
performed on the related behavioral.

frequency

Frequency of a Time Series

Description

This function returns the frequency of a time series. In the case of a sparse `xts()` time series, and in other cases, the R functions `xts::periodicity()` and `frequency()` do not return BIMETS compliant values. We suggest to use this function when a BIMETS time series frequency is requested.

Usage

```r
## S3 method for class 'xts'
frequency(x,...)
```
Arguments

x            Input time series.
...          Backward compatibility.

Value

This function returns the integer value stored in the attribute `.bimetsFreq` of the input time series, if any. Otherwise the frequency will be calculated by using the shortest time difference between two observations, while accounting for daysaving and bissextile years.

See Also

normalizeYP
NUMPERIOD
BIMETS indexing

Examples

```r
# build a sparse xts()
xArr=rnorm(13)
dateArr=seq(as.Date('2000/01/01'),by='6 months',length=10)
dateArr2=seq(as.Date('2010/01/01'),by='3 months',length=3)

dateArr3=c(dateArr,dateArr2)
dataF=data.frame(dateArr3,xArr)
xt=xts(dataF[,2],order.by=dataF[,1])

# get bimets calculated frequency
cat(frequency(xt)) # print 4... without bimets R returns 1

#...legacy periodicity()
periodicity(xt)
```

fromBIMETS to TS

Convert BIMETS to TS

Description

This function transforms a BIMETS compliant time series (as defined in `is.bimets`) into a time series of class `ts()`. The core R function `as.ts()` does not satisfy all the requirements of the compliance control check, so it has been extended. Attributes and description of the input time series will be copied to the output time series (see `TIMESERIES`).
fromBIMETStoTS generates a time series object that satisfies the compliance control check defined in the `is.bimets` function.

**Usage**

```r
fromBIMETStoTS(x = NULL, ...)  
```

**Arguments**

- `x`: Input time series that must satisfy the compliance control check defined in `is.bimets`.  
- `...`: Backward compatibility.

**Value**

This function returns a time series object of class `ts()` that has the same observations of the input BIMETS time series.

**See Also**

- `fromBIMETStoXTS`
- `as.bimets`
- `is.bimets`
- `BIMETS indexing`
- `BIMETS configuration`

**Examples**

```r
# work with XTS
setBIMETSconf('BIMETS_CONF_CCT','XTS')

# create yearly time series
xts=TSERIES(1:10,START=c(2000,1),FREQ='A')
print(is.ts(xts))#FALSE
# convert to ts
ts=fromBIMETStoTS(xts)
print(is.ts(ts))#TRUE
print(ts)

# create monthly time series
xts=TSERIES(1:10,START=c(2000,1),FREQ='M')
print(is.ts(xts))#FALSE
# convert to ts
ts=fromBIMETStoTS(xts)
print(is.ts(ts))#TRUE
print(ts)

# create daily time series
xts=TSERIES(1:10,START=c(2000,1),FREQ='D')
print(is.ts(xts))#FALSE
# convert to ts
ts=fromBIMETStoTS(xts)
print(is.ts(ts))#TRUE
```
fromBIMETS to XTS

print(ts)

#reset default
setBIMETSconf('BIMETS_CONF_CCT','TS')

fromBIMETS to XTS

Convert BIMETS to XTS

Description

This function transforms a BIMETS compliant time series (as defined in is.bimets) into a time series of class xts().

The core XTS function as.xts() does not satisfy all the requirements of the compliance control check, so it has been extended. If the output time series will have an .indexClass of type Date(), i.e. neither monthly nor quarterly, the output dates will be chosen accordingly to the BIMETS option BIMETS_CONF_DIP: if this option is set to LAST (default), the output xts() time series will have the date of the period set equal to the last day in the same period, e.g. 31 December for yearly time series, 30 June for semiannual, etc.; if the BIMETS option BIMETS_CONF_DIP is set to FIRST, the output xts() time series will have the date of the period set equal to the first day in the same period, e.g. 1 January for yearly time series, 1 July for semiannual time series on the second period, etc.

In the case of quarterly time series the .indexClass=yearqtr; in the case of monthly time series the .indexClass=yearmon.

Attributes and description of the input time series will be copied to the output time series (see TIMESERIES)

Usage

fromBIMETS to XTS(x = NULL, ...)

Arguments

x Input time series that must satisfy the compliance control check defined in is.bimets.

... Backward compatibility.

Value

This function returns a time series of class xts() that has the same observations of the input BIMETS time series.

print(xts)#dates on Jan 1

#reset default
setBIMETSconf('BIMETS_CONF_DIP','LAST')

---

fromTStoXTS  Convert TS to XTS

Description

This function transforms a BIMETS compliant ts time series (as defined in is.bimets) into a time series of class xts().
The core XTS function \texttt{as.xts()} does not satisfy all the requirements of the compliance control check, so it has been extended. If the output time series has an \texttt{.indexClass} of type \texttt{Date()}, i.e. neither monthly nor quarterly, the output dates are chosen accordingly to the BIMETS option \texttt{BIMETS_CONF_DIP}: if this option is set to \texttt{LAST} (default), the output \texttt{xts()} time series will have the date of the period set equal to the last day in the same period, e.g. 31 December for yearly time series, 30 June for semiannual, etc.; if BIMETS option \texttt{BIMETS_CONF_DIP} is set to \texttt{FIRST}, the output \texttt{xts()} time series will have the date of the period set equal to the first day in the same period, e.g. 1 January for yearly time series, 1 July for semiannual time series on the second period, etc. In the case of quarterly time series the \texttt{.indexClass=yearqtr}; in the case of monthly time series the \texttt{.indexClass=yearmon}.

Attributes and description of the input time series will be copied to the output time series (see \texttt{TIMESERIES}).

Usage

\begin{verbatim}
fromTStoXTS(x = NULL, avoidCompliance = FALSE, ...)
\end{verbatim}

Arguments

\begin{itemize}
\item \texttt{x} \hspace{1cm} Input ts time series that must satisfy the compliance control check defined in \texttt{is.bimets}.
\item \texttt{avoidCompliance} \hspace{1cm} If \texttt{TRUE}, compliance control check of input time series will be skipped. See \texttt{is.bimets}.
\item \texttt{...} \hspace{1cm} Backward compatibility.
\end{itemize}

Value

This function returns a time series of class \texttt{xts()} that has the same observations of the input ts time series.

See Also

**GETDATE Retrieve Dates of Time Series**

**Description**

This function returns the dates array of selected observations, in the requested print format. Dates will be provided accordingly to the BIMETS configuration option BIMETS_CONF_DIP (see BIMETS configuration)

**Usage**

GETDATE(x=NULL, index=NULL, format='%Y-%m-%d', avoidCompliance=FALSE, ...)
Arguments

\textbf{x} \quad \text{Input time series that must satisfy the compliance control check defined in \texttt{is.bimets}.}

\textbf{index} \quad \text{Index of observations to be selected. The output dates will be the dates of the selected observations. If \texttt{index=NULL} this function will retrieve all available dates in the input time series.}

\textbf{format} \quad \text{Output print format, provided as a paste of the following codes:}
\begin{itemize}
  \item \texttt{%Y}: 4 digits year
  \item \texttt{%y}: 2 digits year
  \item \texttt{%j}: period in the year for daily time series
  \item \texttt{%q}: quarter index, available only if also \texttt{%y} or \texttt{%Y} have been requested
  \item \texttt{%m}: 2 digits month
  \item \texttt{%b}: 3 digits month
  \item \texttt{%B}: full month name
  \item \texttt{%d}: 2 digits day
  \item \texttt{%a}: 3 letters weekday
  \item \texttt{%A}: full weekday name
\end{itemize}

\textbf{avoidCompliance} \quad \text{If TRUE, compliance control check of input time series will be skipped. See \texttt{is.bimets}}

\textbf{...} \quad \text{Backward compatibility.}

Value

This function returns the dates array of selected observations, in the requested print format.

**GETYEARPERIOD**

*Get Time Series Year-Period*

**Description**

This function returns a two-element list (or a two-columns matrix in the case of JOIN=TRUE) built with the the years and the periods of the input time series observations. Users can provide the output list names. TSDATES is an alias for GETYEARPERIOD.
GETYEARPERIOD

Usage

GETYEARPERIOD(x=NULL, YEARS='YEAR', PERIODS='PRD', JOIN=FALSE, avoidCompliance=FALSE, ...)  
TSDATES(x=NULL, YEARS='YEAR', PERIODS='PRD', JOIN=FALSE, avoidCompliance=FALSE, ...)

Arguments

x Input time series, that must satisfy the compliance control check defined in is.bimets
YEARS Argument of type string that will be the output list name for the array of observation years.
PERIODS Argument of type string that will be the output list name for the array of observation periods.
JOIN If TRUE, the output will be a matrix having each row built with the year and the period of the related observation.
avoidCompliance If TRUE, compliance control check of input time series will be skipped. See is.bimets
... Backward compatibility.

Value

This function returns an object of class list(). If JOIN=TRUE, this function returns a matrix.

**BIMETS Time Series Indexing**

**Description**

The package extends the way users can access and modify time series data in order to ease time series analysis and manipulation.

**SELECTING BY DATE**: users can select a single observation by date by using the syntax `ts['Date']` and multiple observations by using `ts['StartDate/EndDate']` or `ts['StartDate'+(0:n)/f]`, with `f=frequency,n=#observations`. Data modification follows the same syntax:

`ts['Date']=value,ts['Date']=c(value,value,...,value),` etc. Users can also provide the string representing only the year of selection, or the year and the month of selection. For quarterly and monthly time series it is possible to select dates by using instances of class `yearmon()` and `yearqtr()` (See examples).

**SELECTING BY YEAR-PERIOD**: Users can select observations by providing the year and the period requested. Selection and modification of data require the double square bracket syntax, e.g. `ts[[YEAR,PERIOD]]=value`. Users can also assign an array of values to the input time series, starting from the `[[YEAR,PERIOD]]` provided, i.e. `ts[[YEAR,PERIOD]]=c(value1,value2,...,valueN)`; in this case the input time series will be eventually extended in order to sequentially insert all values of the provided array (See examples).

**SELECTING BY INDEXES**: (core R) Users can select observations by simply providing the array of requested indexes, e.g. `ts[c(idx1,idx2,...,idxN)]` while reading and `ts[c(idx1,idx2,...,idxN)]=c(value1,value2,...,valueN)` while writing time series data.

---

INDEXNUM

*Rebase a Time Series*

**Description**

This function rebases an input time series to the value of 100 in the year selected by the `BASEYEAR` argument. If the input time series frequency is greater than one, the initial reference is set to the average value of the input time series observations that lie in the `BASEYEAR`.

**Usage**

`INDEXNUM(x=NULL, BASEYEAR=NULL, avoidCompliance=FALSE, ...)`

**Arguments**

- `x` Input time series that must satisfy the compliance control check defined in `is.bimets`.
- `BASEYEAR` Rebasing year.
- `avoidCompliance` If TRUE, compliance control check of input time series will be skipped. See `is.bimets`
- `...` Backward compatibility.

**Value**

This function returns a BIMETS time series.

### Description

A command such \( \text{INTS}(i, j) \) returns a one-dimensional array built with the integers \( i, i+1, i+2, \ldots, j \) when \( i, j \) are both scalars, and \( j \) is greater than \( i \). When \( j \) is less than \( i \), the command shown above defines a one-dimensional array built with the integers \( i, i-1, i-2, \ldots, j \).

Users can specify the \( k \) increment with a syntax like \( \text{INTS}(i, j, k) \) which defines a one-dimensional array built with the values \( i, i+k, i+2k, \ldots, i+Nk \).

The value of the last element of the array is the maximum value of \( i+Nk \) that is less than or equal to \( j \), for positive \( k \). For negative \( k \), the value of the last element of the array is the minimum value of \( i+Nk \) that is greater than or equal to \( j \).

The command can be used with one parameter by using a syntax like \( \text{INTS}(i) \) where \( i \) is a positive scalar. The result is a one-dimensional array built with the integers \( 1, 2, 3, \ldots, i \). When \( i \) is less than 1, the array is built with the integers \(-1, -2, \ldots, -i\).

### Usage

\( \text{INTS} \) \( \text{FROM} = \text{NULL}, \ \text{TO} = \text{NULL}, \ \text{BY} = \text{NULL}, \ldots \)
Arguments

FROM  The first integer of the sequence. If arguments TO and BY are NULL and FROM>0 the sequence will start from 1 and will end in FROM; If arguments TO and BY are NULL and FROM<0 the sequence will start from -1 and will end in FROM (see examples).

TO  The last integer of the sequence.

BY  Increment between two elements of the sequence.

...  Backward compatibility.

Value

This function returns an object of class c().

is.bimets

Check the Compliance of a Time Series

Description

This function checks the compliance of the input time series that must verify the following BIMETS requirements:

- the input time series must be of the class defined in BIMETS_CONF_CCT (see BIMETS configuration)

- If BIMETS_CONF_CCT='TS' the input time series must be of class ts, univariate, with at least one observation and with a frequency $f=1,2,3,4,12,24,36,53$ or $366$ per year.

- If BIMETS_CONF_CCT='XTS' the input time series must be of class xts, univariate, with at least one observation and with a frequency $f=1,2,3,4,12,24,36,53$ or $366$ per year; the input time series must also be strictly regular, i.e. without any temporal discontinuity, and must have an .indexClass of type yearmon() for monthly time series, of type yearqtr() for quarterly time series and of type Date() for any other frequency. If configuration option BIMETS_CONF_DIP='LAST', i.e. the default value, the provided observation dates of the input xts() time series must be the last dates in the period, e.g. Dec. 31 for yearly time series, Jun. 30 for the first period in a semiannual time series, etc.; If configuration option BIMETS_CONF_DIP='FIRST' the provided observation dates of the input xts() time series must be the first dates in the period, e.g. Jan. 1 for an yearly time series, Jul. 1 for the second period in a semiannual time series, etc.;

BIMETS package functions return time series that are compliant to the above requirements.

The compliance check can be locally disabled by using the function argument avoidCompliance=TRUE, that is available in almost all package functions. The compliance check of a BIMETS generated time series can be avoided and disabling the control check can speed up the execution time. This is suggested when users concatenate several call to the package functions, e.g. the compliance check of the ts2 time series in the following example can be avoided:

```r
  ts2=TSLAG(ts1); ts3=TSDELTA(ts2, avoidCompliance=TRUE);
```

Time series must lie in the year range 1800-2199: in this range the conversion between a date and the related year-period (and vice versa) has been hardcoded in order to speedup the execution time.

If the compliance check is disabled, i.e. avoidCompliance=TRUE and the input time series does not verify all the above requirements, the package functions can have an erroneous behavior. Should any doubt arise, we suggest to call the package functions using the default arguments; we also suggest to create time series object by using the command TIMESERIES.

Usage

```r
  is.bimets(x = NULL, suppressErrors=TRUE, ...)
```
Arguments

x  Input time series.
suppressErrors  If suppressErrors=TRUE the function returns a logical value TRUE/FALSE whenever the input time series is BIMETS compliant. If suppressErrors=FALSE the function will throw an error if the input time series is not BIMETS compliant.

Value

This function returns a logical value TRUE/FALSE whenever the input time series is compliant to the above BIMETS requirements. If the test fails and suppressErrors=FALSE this function will throw an error.

# Load a BIMETS model description file

## Description

This function parses a MDL model definition and creates an equivalent R data structure that can be estimated and simulated. The input model definition can be either an external plain text file or a character variable.

## Usage

```r
LOAD_MODEL( modelFile=NULL,
            modelText=NULL,
            showWarnings=TRUE,
            quietly=FALSE,
            oldStyleModel=FALSE,
            ...
            )
```

## Arguments

- **modelFile** The path to the text file containing the MDL model definition.
- **modelText** The character variable containing the MDL model definition. modelText takes precedence over modelFile if both are defined.
- **showWarnings** If TRUE a warning message will be shown if the model has a null set of endogenous variables or a null set of exogenous variables.
- **quietly** If TRUE, information messages will be suppressed.
- **oldStyleModel** Backward compatibility.
- **...** Backward compatibility.
Value

This function returns a BIMETS model object containing all the information gathered from the parsing of the input model definition.

A BIMETS model created with the LOAD_MODEL function can be viewed as a complex R list() containing the following elements (see examples):

- `rawData` and `cleanModel`: string arrays containing the original model definition. cleanModel is a clean version of the model definition, i.e. without comments, blank lines, etc.;

- `behaviorals` and `identities`: sub-lists containing all the information gathered from the behavioral and the identity definitions. This sub lists are described later in this page;

- `vendog` and `vexog`: string array containing the names of the endogenous and exogenous variables of the model; the former is also subsetted into `vendogBehaviorals` and `vendogIdentities`

- `totNumEqs`, `totNumIds` and `eqCoeffNum`: integer variables containing the behaviorals count, the identities count and the coefficients count of the model;

- `incidence_matrix`: the incidence matrix built from the model equations; it is a square matrix in which each row and each column represent an endogenous variable. If the \((i,j)\) element is equal to 1 than in the model definition the current value of the endogenous variable referred by the \(i\)-row directly depends on the current value of the endogenous variable referred by the \(j\)-column. (see example)

- `vpre`, `vsim`, `vfeed` and `vpost`: the simulation process takes advantage of an appropriate ordering of the equations to increase the performances by iteratively solving only one subset of equations, while the other equations are solved straightforwardly. (Ref: Don Gallo - Solving large sparse systems of equations in econometric models - Journal of Forecasting 1987 and Numerical methods for simulation and optimal control of large-scale macroeconomic models - Nepomiaistchy, Rachidi, Ravelli - 1980). The optimal reordering of the model equations is achieved by using an iterative algorithm applied to the incidence matrix, that produces 4 ordered arrays of endogenous variables:
  1) `vpre` is the ordered string array containing the names of the endogenous pre-recursive variables that must be computed (by using their EQ> definition) before the simulation iterative algorithm takes place;
  2) `vsim` is the ordered string array containing the names of the endogenous variables that must be sequentially computed during each iteration of the simulation algorithm;
  3) `vfeed` is the ordered string array containing the names of the endogenous feedback variables to be evaluated for convergence during the simulation iterative algorithm;
  4) `vpost` is the ordered string array containing the names of the endogenous post-recursive variables that must be computed after the execution and the convergence of the iterative algorithm in step 3 (more details in BIMETS package and SIMULATE help pages);

- `max_lag`: the max lag of the model, i.e. the highest number of periods a time series of the model is lagged by in the MDL definition. It also accounts for PDLs and for the order of the error autocorrelation, if any;

- `modelName`: the name of the model, copied from the input file name or from the input character
variable name containing the model definition;

BEHAVIORALS and IDENTITIES

The elements 'behaviorals' and 'identities' of the BIMETS model are named lists that contain information on behaviors and identities of the model. In both of these two lists, the name of each element is the name of the behavioral or the identity the data refer to, as specified in the model definition file: e.g. given a BIMETS model named myModel, the information on a behavioral named cn (i.e. there exists a "BEHAVIORAL> cn" in the MDL definition of the model) is stored into myModel$behaviorals$cn.

Behavioral elements have the following components:

- **eq**: the equation of the behavioral, as a character variable;

- **eqCoefficientsNames**: the names of the coefficients (the original ones and eventually the ones created by the PDL> expansion);

- **eqCoefficientsNamesOriginal**: the names of the original coefficients;

- **eqComponentsNames**: the names of endogenous and exogenous variables that appear in the behavioral equation;

- **eqComponentsNamesBehaviorals**: the names of behavioral endogenous variables that appear in the behavioral equation;

- **eqComponentsNamesIdentities**: the names of identity endogenous variables that appear in the behavioral equation;

- **eqComponentsNamesExogenous**: the names of exogenous variables that appear in the behavioral equation;

- **tsrange**: the estimation time range as a 4 integer array;

- **eqRegressorsNames**: a character array containing the regressor expressions (the original ones and eventually the ones created by the PDL> expansion);

- **eqRegressorsNamesOriginal**: a character array containing the expressions of the original regressors;

- **errorRaw**: the original definition of the error autocorrelation, if any (see MDL);

- **errorType**: the type of the error structure;

- **errorDim**: the dimension of the error autocorrelation;

- **eqSimExp**: the R optimized expression of the behavioral equation that is used in the simulation algorithm;
- **matrixR**: the R Lagrange matrix that is used in restriction analysis (see MDL);

- **vectorR**: the r Lagrange vector that is used in restriction analysis (see MDL);

- **restrictRaw**: the original definition of the coefficient restrictions, if any.

- **pdlRaw**: the original definition of the PDL restrictions, if any (see examples and MDL).

- **pdlRestrictionMatrix**: the R Lagrange matrix that is used in PDL restriction analysis (see examples and MDL);

- **IVComponentsNames**: the names of endogenous and exogenous variables that appear in the instrumental variables equations, if any;

- **iv**: the original definitions of instrumental variables, if any.

For example, given a BIMETS model named myModel, the information on a technical identity named y (i.e. there exists an "IDENTITY> y" in the MDL definition of the model) is stored in myModel$identities$y.

Identity elements have the following components:

- **eqRaw**: the original equations of the identity (more than one if the identity has multiple equations and has IF> conditions), as a character variable (see examples and MDL);

- **ifRaw**: the original IF> conditions, if any, of the identity, as a character variable;

- **eqFull**: the full expression of the identity, composed with IF> conditions and related equations (see examples), as a character variable;

- **eqComponentsNames**: the names of endogenous and exogenous variables that appear in the identity equation;

- **eqComponentsNamesBehaviorals**: the names of behavioral endogenous variables that appear in the identity equation;

- **eqComponentsNamesIdentities**: the names of identity endogenous variables that appear in the identity equation;

- **eqSimExp**: the R optimized expression of the identity equation that is used in the simulation algorithm;

- **hasIF**: boolean, TRUE if the identity has an IF> condition;

#LOAD_MODEL_DATA

LOAD_MODEL_DATA: Load time series data into a BIMETS model object

Description

This function verifies the input time series list and copies the data into a BIMETS model object. Provided time series must be BIMETS compliant, as defined in `is.bimets`.

Usage

LOAD_MODEL_DATA(model=NULL, modelData=NULL, showWarnings=FALSE, quietly=FALSE, ...)

Arguments

- **model**: The BIMETS model object (see `LOAD_MODEL`).
- **modelData**: The input time series list containing endogenous and exogenous data (see example).
- **showWarnings**: If TRUE, a warning message will be shown if any input time series has missing values.
- **quietly**: If TRUE, information messages will be suppressed.
- **...**: Backward compatibility.

Value

This function add a new named element, i.e. `modelData`, into the output model object.

The new `modelData` element is a named R list that contains all the input time series. Each element name of this list is set equal to the name of the endogenous or exogenous variable the time series data refer to.

### LOCS

**Select Time Series Indexes**

#### Description

This function returns the indexes of the input TRUE elements. The input can be either an array or a time series. The result is usually used as a structured index to produce a new array.

#### Usage

```
LOCS(x=NULL, options='ALL', ...)
```
Arguments

x

This function accepts as input a boolean array or a boolean time series, often as the result of a logic comparison between an expression and a numerical array or a numerical time series:
e.g. LOCS(c(a,b,c,...)>=k); LOCS(ts==j);
LOCS(ts<expr); LOCS(is.na(ts)); etc...

options

A selection option can refine the result:
ALL: (default) all the TRUE indices will be returned in the output.
UNIQUE: return the index of the unique TRUE result; if there are multiple TRUE results then an error will be thrown.
FIRST: return the first TRUE result.
LAST: return the last TRUE result.

Value

This function returns a numerical array built with the indexes of the values that are TRUE in the input boolean array or in the input boolean time series.

BIMETS Model Description Language

Description

BIMETS provides a language to unambiguously specify an econometric model. This page describes how to create a model and its general structure. The specification of an econometric model is translated and identified by keyword statements which are grouped in a model file, i.e. a plain text file or a character variable with a specific syntax. Collectively, these keyword statements constitute the BIMETS Model Description Language (from now on MDL). The model specifications consist of groups of statements. Each statement begins with a keyword. The keyword classifies the component of the model which is being specified.

Below is an example of a Klein’s model with a MDL compliant syntax that can either be stored in a character variable or in a plain text file.

The content of the *klein1.txt* variable is:

```plaintext
R> klein1.txt="

EQ> y = cn + i + g - t

COMMENT> Profits
IDENTITY> p
EQ> p = y - (w1+w2)
```
Please note that there are circular dependencies between equations of the model, i.e. \( cn \leftarrow w_1 \leftarrow y \leftarrow cn \). Circular dependencies imply that the model simulation must be solved with an iterative algorithm.

As shown, the model definition is quite intuitive. The first keyword is `MODEL`, while at the end of the model definition we can find the `END` keyword. Available tags in the definition of a generic BIMETS model are:

- `EQUATION>` or `BEHAVIORAL>` indicate the beginning of a series of keyword statements describing a behavioral equation. The behavioral statement general form is:

```
BEHAVIORAL> name [TSRANGE startYear,startPeriod,endYear,endPeriod]
```

where `name` is the name of the behavioral equation and the optional `TSRANGE` specifies that the provided time interval must be used in the coefficients estimation. The optional `TSRANGE` is defined as a 4-dimensional numerical array built with starting year, starting period, ending year and ending period.

Given \( Y = \beta \ast X + \epsilon \), where \( Y \) are the historical values of the dependent variable and \( X \) are the historical values of the regressors, if the requested estimation method is OLS (Ordinary Least Squares), in the general case (i.e. no restrictions nor error auto-correlation, as described later) the coefficients will be calculated as: \( \beta_{OLS} = (X' \ast X)^{-1} \ast X' \ast Y \).

If the requested estimation method is IV (Instrumental Variables), given \( Z \) the matrix built with instrumental variables as columns \( Z_i \), that should not be correlated to the disturbance terms, i.e. \( E[\epsilon' \ast Z_i] = 0 \), the coefficients will be either calculated as \( \beta_{IV} = (Z' \ast X)^{-1} \ast Z' \ast Y \), or more generally as: \( \beta_{IV} = (\hat{X}' \ast \Omega^{-1} \ast \hat{X})^{-1} \ast \hat{X}' \ast \Omega^{-1} \ast Y \) where \( \hat{X} = Z \ast (Z' \ast Z)^{-1} \ast Z' \ast X \) and \( \Omega = \sigma^2 \ast I \), \( \sigma^2 = E[\epsilon' \ast \epsilon] \).

- `IDENTITY>` indicates the beginning of a series of keyword statements describing an identity or technical equation. The identity statement general form is:

```
IDENTITY> name
```

where `name` is the identity name.

- `EQ>` specifies the mathematical expression for a behavioral or an identity equation.

The equation statement general form for a behavioral equation is:

```
EQ> LHS = coeff1*f1 + coeff2*f2 + coeff3*f3 + ...
```

where `LHS` is a function of the behavioral variable, `coeff1,coeff2,coeff3,...` are the coefficient names of the equation and `f1,f2,f3,...` are functions of variables.

The equation statement general form for an identity equation is:

```
EQ> LHS = f1 + f2 + f3 + ...
```
where LHS is a function of the identity variable and f1, f2, f3, ... are functions of variables.

The following MDL functions can be used in the LHS left-hand side of the equation, with name as the name of the behavioral or the identity variable:

- name - i.e. the identity function;
- TSDELTA(name, i) - i-periods difference of the name time series;
- TSDELTAP(name, i) - i-periods percentage difference of the name time series;
- TSDELTALOG(name, i) - i-periods logarithmic difference of the name time series;
- LOG(name) - log of the name time series;
- EXP(name) - exponential of the name time series.

On the other side the mathematical expression available for using in the RHS right-hand side of the EQ> equation and in the IV> expression described later in this page (i.e. f1, f2, f3, ...) can include the standard arithmetic operators, parentheses and the following MDL functions:

- TSLAG(ts, i) - lag the ts time series by i-periods;
- TSDELTA(ts, i) - i-periods difference of the ts time series;
- TSDELTAP(ts, i) - i-periods percentage difference of the ts time series;
- TSDELTALOG(ts, i) - i-periods logarithmic difference of the ts time series;
- MOVAVG(ts, i) - i-periods moving average of the ts time series;
- MOVSUM(ts, i) - i-periods moving sum of the ts time series;
- LOG(ts) - log of the ts time series;
- EXP(ts) - exponential of the ts time series;
- ABS(ts) - absolute values of the ts time series.

MDL function names are reserved names. They cannot be used as variable or coefficient names. The coefficient names are specified in a subsequent COEFF> keyword statement within a behavioral equation. By definition, identities do not have any coefficient that must be assessed. Any name not specified as a coefficient name or mentioned on the list of the available MDL functions is assumed to be a variable.

- COEFF> specifies the coefficient names used in the EQ> keyword statement of a behavioral equation. The coefficients statement general form is:
The coefficients order in this statement must be the same as it appears in the behavioral equation.

- **ERROR>** specifies an autoregressive process of a given order for the regression error. The error statement general form is:

  ERROR> AUTO(n)

  where \( n \) is the order of the autoregressive process for the error.

During an estimation, users must ensure that the required data is available for the specified error structure: \( n \) periods of data prior to the time interval specified by \( TSRANGE \) are requested in any time series involved in the regression.

The solution requires an iterative algorithm. Given \( Y_1 = \beta_1 \cdot X_1 + \epsilon_1 \), where \( Y_1 \) are the historical values of the dependent variable and \( X_1 \) are the historical values of the regressors, the iterative algorithm is based on the Cochrane-Orcutt procedure:

1) Make an initial estimation by using the original \( TSRANGE \) extended backward \( n \) periods (given \( n \) as the autocorrelation order).

2) estimate the error autocorrelation coefficients \( \rho_i = \rho_{i,1}, ..., \rho_{i,n} \) with \( i = 1 \) by regressing the residuals \( \epsilon_i \) on their lagged values by using the auxiliary model:

\[
\epsilon_i = \rho_{i,1} * TSLAG(\epsilon_i, 1) + \ldots + \rho_{i,n} * TSLAG(\epsilon_i, n)
\]

3) transform the data for the dependent and the independent variables by using the estimated \( \rho_i \).

   The new dependent variable will be: \( Y_{i+1} = P_i \cdot Y_i \), and the new independent variables will be \( X_{i+1} = P_i \cdot X_i \) with the matrix \( P_i \) defined as:

\[
P_i = \begin{pmatrix}
1 & 0 & 0 & 0 & \ldots & 0 & 0 \\
-\rho_{i,1} & 1 & 0 & 0 & \ldots & 0 & 0 \\
-\rho_{i,2} & -\rho_{i,1} & 1 & 0 & \ldots & 0 & 0 \\
0 & 0 & \ldots & -\rho_{i,n} & \ldots & -\rho_{i,1} & 1 \\
\end{pmatrix}
\]

4) run another estimation on the original model \( Y_{i+1} = \beta_{i+1} \cdot X_{i+1} + \epsilon_{i+1} \) by using the suitable \( TSRANGE \) and the transformed data coming out of step 3 and compute the new time series for the residuals.

5) estimate the new autocorrelation coefficients \( \rho_{i+1} = \rho_{i+1,1}, ..., \rho_{i+1,n} \), by regressing the new residuals arising from step 4 (similar to step 2)

6) carry out the convergence check through a comparison among the previous \( \rho_i \) and the new ones arising from steps 5.

   If \( \text{all} (\text{abs}(\rho_{i+1} - \rho_i) < \delta) \), where \( \rho_i \) is the \( \rho \) vector at the iteration \( i \) and \( \delta \) is a small convergence factor, then exit otherwise repeat from step 3 with \( i < i+1 \).

- **RESTRICT>** is a keyword that can be used to specify linear coefficient restrictions. A deterministic restriction can be applied to any equation coefficient. Any number of **RESTRICT>** keywords is allowed for each behavioral equation.
A deterministic (exact) coefficient restriction sets a linear expression containing one or more coefficients equal to a constant. The restriction only affects the coefficients of the behavioral equation in which it is specified. The restriction statement general form is:

\[
\text{RESTRICT} > \, \text{linear_combination_of_coefficients}_1 = \text{value}_1 \\
\quad \ldots \\
\quad \text{linear_combination_of_coefficients}_n = \text{value}_n
\]

where \( \text{linear_combination_of_coefficients}_i, i=1..n \) is a linear combination of the coefficient(s) to be restricted and \( \text{value}_i \) is the in-place scalar value to which the linear combination of the coefficients is set equal. Each linear combination can be set equal to a different value.

MDL example:

\[
\text{RESTRICT} > \, \text{coeff1} = 0 \\
\text{coeff2} = 10.5 \\
\text{coeff3} - 3 \times \text{coeff4} + 1.2 \times \text{coeff5} = 0
\]

In many econometric packages, linear restrictions have to be coded by hand in the equations. BIEMS allows the users to write down the restriction in a natural way thus applying a constrained minimization. This procedure, although it leads to approximate numerical estimates, allows an easy implementation.

The theory behind this procedure is that of the Lagrange multipliers. Presented here is an example of its implementation.

Suppose that we have an equation defined as:

\[
\text{EQUATION} > \, \text{Y TSRANGE} \, 2010 \, 1 \, 2015 \, 4 \\
\text{EQ} > \, \text{Y} = \, \text{C1} \times \text{X1} + \, \text{C2} \times \text{X2} + \, \text{C3} \times \text{X3} \\
\text{COEFF} > \, \text{C1} \, \text{C2} \, \text{C3} \\
\text{RESTRICT} > \, 1.1 \times \text{C1} + \, 1.3 \times \text{C3} = 2.1 \\
\quad 1.2 \times \text{C2} = 0.8
\]

Coefficients \( \text{C1}, \text{C2}, \text{C3} \) are to be estimated. They are subject to the linear constraints specified by the \text{RESTRICT} keyword statement. In the case of OLS estimation, this is carried out in the following steps:

1) Compute the cross-product matrices \( X'X \) and \( X'Y \) where \( X \) is a matrix with dimension \([\text{NOBS} \times \text{NREG}]\) containing the values of the independent variables (regressors) historical observations (and a vector of ones for the constant term, if any), and where \( Y \) is a \text{NOBS} elements vector of the dependent variable (regressand) historical observations; \text{NOBS} is the number of observations available on the \text{TSRANGE} specified in the behavioral equation and \text{NREG} is the number of regressors, or coefficients;

2) Build the restriction matrices. In the example:

\[
R = \begin{pmatrix}
1.1 & 0 & 1.3 \\
0 & 1.2 & 0
\end{pmatrix}
\]
and

\[ r = \begin{pmatrix} 2.1 \\ 0.8 \end{pmatrix} \]

\( R \) is a matrix of \([NRES \times NREG]\) size and \( r \) is a vector of \([NRES]\) length, where \( NRES \) is the number of restrictions;

3) Compute the scaling factors for the augmentation to be performed in the next step:

\[ Rscale[i] = \frac{mean(X'X)}{\max(abs(R[i,]))} \]

where \( R[i,] \) is the i-th row of the \( R \) matrix.

Assuming \( mean(X'X) = 5000 \), in the example above we will have:

\[ Rscale[1] = \frac{5000}{1.3} \]
\[ Rscale[2] = \frac{5000}{1.2} \]

The augmented matrices will then be defined as:

\[ R_{aug} = \begin{pmatrix} 1.1Rscale[1] & 0 & 1.3Rscale[1] \\ 0 & 1.2Rscale[2] & 0 \end{pmatrix} \]

and

\[ r_{aug} = \begin{pmatrix} 2.1Rscale[1] \\ 0.8Rscale[2] \end{pmatrix} \]

4) Compute the so-called "augmented" cross-product matrix \((X'X)_{aug}\) by adding to the cross-product matrix \((X'X)\) a total of \( NRES \) rows and \( NRES \) columns:

\[ (X'X)_{aug} = \begin{pmatrix} X'X & R'_{aug} \\ R_{aug} & 0 \end{pmatrix} \]

5) In a similar way, compute the so-called "augmented" cross-product matrix \((X'Y)_{aug}\) by adding a total of \( NRES \) elements to the cross-product matrix \((X'Y)\):

\[ (X'Y)_{aug} = \begin{pmatrix} X'Y \\ Y_{aug} \end{pmatrix} \]

6) Calculate the \( \hat{\beta}_{aug} \) augmented coefficients by regressing the \((X'Y)_{aug}\) on the \((X'X)_{aug}\).

The first \( NREG \) values of the augmented coefficients \( \hat{\beta}_{aug} \) array are the estimated coefficients with requested restrictions. The last \( NRES \) values are the errors we have on the deterministic restrictions.

In the case of IV estimation the procedure is the same as in the OLS case, but the matrix \( X \) has to be replaced with the matrix \( \hat{X} \), as previously defined in the BEHAVIORAL> keyword.

- **PDL>** is a keyword that defines an Almon polynomial distributed lag to be used in an estimation. Almon Polynomial distributed lags are specific kind of deterministic restrictions imposed on the coefficients of the distributed lags of a specific regressor. Multiple PDLs on a single behavioral equation can be defined.
The PDL> statement general form is:
\[ \text{PDL> coeffname degree laglength [N] [F]} \]
where **coeffname** is the name of a coefficient, **degree** is an integer scalar specifying the degree of the polynomial, **laglength** is an integer scalar specifying the length of the polynomial (in number of time periods), the optional **N** (i.e. "nearest") means that the nearest lagged term of the expansion, i.e., the first term, is restricted to zero, and the optional **F** (i.e. "farthest") means that the farthest lagged term of the expansion, i.e., the last term, is restricted to zero; the PDL> keyword statement thusly defined applies an Almon polynomial distributed lag to the regressor associated with the **coeffname** coefficient, of **laglength** length and **degree** degree, by providing the appropriate expansion and the deterministic restrictions for the degree and length specified. These expansions are not explicitly shown to the user, i.e., the original model is not changed.

**laglength** must be greater than **degree** (see example below).

A PDL term can be further referenced in a RESTRICT> keyword statement by using the following syntax: LAG(coefname,pdllag).

Example: RESTRICT> LAG(coeff2,3) = 0 means that, during the estimation, the regressor related to the coefficient **coeff2** and lagged by 3 periods in the PDL expansion must have a coefficient equal to zero. This example also implies that a PDL> coeff2 x y with \( y > 3 \) has been declared in the same behavioral.

The implementing rules are the following:

1) Read off the **laglength** of the PDL keyword and expand the column of the regressor related to **coeffname** in the matrix **X** (i.e. the original regressors matrix) with the lagged values of the regressor, from the left to the right, starting form the lag 1 to the lag **laglength-1**. The matrix **X** will now have a \([\text{NOBS} \times (\text{NREG}+\text{laglength}-1)]\) size, with **NOBS** as the number of observations in the specified TSRange and **NREG** as the number of regressors, or coefficients.

2) Build the restriction matrix **R** with the following \([\text{Nrow} \times \text{Ncol}]\) dimensions:
\[ \text{Nrow} = \text{laglength} - (\text{degree} + 1) \]
\[ \text{Ncol} = \text{NREG} + \text{laglength} - 1 \]

The elements of this matrix will be zero except for the \((\text{laglength})\)-columns related to the section of the expanded columns in the **X** matrix. For every row we will have to insert **degree+2** numbers different from zero.

The **degree+2** numbers are taken form the Tartaglia's-like triangle:
\[
\begin{array}{cccc}
1 & -2 & 1 \\
1 & -3 & 3 & -1 \\
1 & -4 & 6 & -4 & 1 \\
1 & -5 & 10 & -10 & 5 & 1 \\
\cdots & \cdots & \cdots & \cdots & \cdots & \cdots \\
\end{array}
\]

where in the \(i\)-th row we find the numbers for a PDL of degree=\(i\).
The $r$ vector giving the knows terms for the restrictions is a vector of $NRES = \text{laglength} - (\text{degree} + 1)$ elements equal to zero.

An example will clarify:

\textbf{EQUATION}> Y TSRANGE 2010 1 2015 4
\textbf{EQ}> Y = C1*X1 + C2*X2 + C3*X3
\textbf{COEFF}> C1 C2 C3
\textbf{PDL}> C2 2 5

then

$$R = \begin{pmatrix} 0 & 1 & -3 & 3 & 1 & 0 & 0 \\ 0 & 0 & 1 & -3 & 3 & 1 & 0 \end{pmatrix}$$

and

$$r = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

The expanded regressors are: $X1, X2, \text{TSLAG}(X2, 1), \text{TSLAG}(X2, 2), \text{TSLAG}(X2, 3), \text{TSLAG}(X2, 4), X3$.

The scaling factor is given, as in the standard restriction case, by: $\text{mean}(X'X)/\text{max}(\text{abs}(R[i,]))$

- \textbf{IF}> keyword is used to conditionally evaluate an identity during a simulation, depending on the value of a logical expression. Thus, it is possible to have a model alternating between two or more identity specifications for each simulation period, depending upon results from other equations.

The \textbf{IF}> statement general form is:

\textbf{IF}> logical\_expression

The \textbf{IF}> keyword must be specified within an identity group; this keyword causes the equation specified in the identity group to be evaluated during the current simulation period only when the \textit{logical\_expression} is TRUE.

Only one \textbf{IF}> keyword is allowed in an identity group. Further occurrences produce an error message and processing stops.

The \textit{logical\_expression} can be composed of constants, endogenous variables, exogenous variables, an expression among variables, combinations of the logical operators; mathematical operators and the \texttt{MDL} functions listed in the \textbf{EQ}> section are allowed.

In the following \texttt{MDL} example, the value of the endogenous \textit{myIdentity} variable is specified with two complementary conditional identities, depending on the \texttt{TSDELTA()} result:

\textbf{IDENTITY}> myIdentity
\textbf{IF}> TSDELTA(myEndog*(1-myExog)) > 0
EQ> myIdentity = TSLAG(myIdentity)*I

IDENTITY> myIdentity
IF> TSDELTA(myEndog*(1-myExog)) <= 0
EQ> myIdentity = TSLAG(myIdentity)

- IV> specifies the mathematical expression for an instrumental variable used in a behavioral equation.

The general form for an instrumental variable expression is:
IV> f1 + f2 + f3 + ...
f1, f2, f3, ... are functions of variables.

The mathematical expression available for using in the IV> definition are those already described in the EQ> section.

- COMMENT> can be used to insert comments into a model. The general form of this keyword is:
COMMENT> text

The text following the COMMENT> keyword is ignored during all processing, and must lie in the same line. A comment cannot be inserted within another keyword statement. A dollar sign in the first position of a line is equivalent to using the COMMENT> keyword, as in this example:
$This is a comment

No other keywords are currently allowed in the MDL syntax.

MONTHLY

MONTHLY (Dis)Aggregation

Description

This function returns a monthly (dis)aggregated time series, by using as input an annual, semiannual, quarterly or daily time series.

Usage

MONTHLY(x = NULL, fun = NULL, avoidCompliance = FALSE, ...)

Arguments

x

Input time series that must satisfy the compliance control check defined in `is.bimets`.

fun

Only for daily input time series:

- **STOCK**: the value of the input time series in the last observation of a month is assigned to the same month of the output time series.
- **NSTOCK**: the value of the input time series in the last non-missing observation of a month is assigned to the same month of the output time series.
- **SUM**: the sum of input observations in a month is assigned to the same month of the output time series.
- **NSUM**: the sum of input non-missing observations in a month is assigned to the same month of the output time series.
- **AVE**: the average of input observations in a month is assigned to the same month of the output time series.
- **NAVE**: the average of input non-missing observations in a month is assigned to the same month of the output time series.

Only for quarterly, semiannual or annual input time series:

- **NULL**: (default) the output value of each monthly observation is set equal to the value of the input observation the month belongs to (i.e. duplicated values over the period)
- **INTERP_END**: the value of the input time series in a period is copied into the last month of the output time series that lies in the same period. Other values are calculated by linear interpolation.
**MOAVG**

**INTERP_CENTER**: the value of the input time series in a period is copied into the median month of the output time series that lies in the same period. Other values are calculated by linear interpolation.

**INTERP_BEGIN**: the value of the input time series in a period is copied into the first month of the output time series that lies in the same period. Other values are calculated by linear interpolation.

**avoidCompliance**

If TRUE, compliance control check of input time series will be skipped. See `is.bimets`

... Backward compatibility.

**Value**

This function returns a monthly BIMETS time series.

**See Also**

SEMIANNUAL
QUARTERLY
DAILY

**Examples**

```
#TS FREQ 2 SEMIANNUAL TO MONTHLY
ts1=TSERIES((1:10),START=c(2000,1),FREQ=2)
TABIT(MONTHLY(ts1,fun='INTERP_CENTER'))

#TS DAILY TO MONTHLY
ts1=TSERIES((1:366),START=c(2000,1),FREQ='D')
TABIT(MONTHLY(ts1,fun='STOCK'))
```

**MOVAVG**

*Moving Average*

**Description**

This function returns the moving average of the elements of the input array or the input time series. The result is an object of the same class of the input, and its elements are the moving average of length L of the input values. If the input is a time series, the DIRECTION of the moving average, i.e. backward, forward or centered, can be provided. `MAVE` is an alias for `MOVAVG`
Usage

MOVAVG(x = NULL, L = NULL, DIRECTION = NULL, avoidCompliance = FALSE, ...)
MAVE(x = NULL, L = NULL, DIRECTION = NULL, avoidCompliance = FALSE, ...)

Arguments

x
Input numerical array or time series that must satisfy the compliance control check defined in is.bimets.

L
Length of the mean. Must be a positive integer.

DIRECTION
if x is a time series, given y as output and x as input:
AHEAD: the output observation value in index n will be $y[n] = \text{mean}(x[n], x[n+1], \ldots, x[n+L-1])$.
CENTER: the output observation value in index n will be $y[n] = \text{mean}(x[n-\text{trunc}(L/2)], \ldots, x[n], x[n+1], \ldots, x[n+\text{trunc}(L/2)])$.
NULL or BACK: (default) the output observation value in index n will be $y[n] = \text{mean}(x[n+1-L], \ldots, x[n-1], x[n])$.

avoidCompliance
If TRUE, compliance control check of input time series will be skipped. See is.bimets

... Backward compatibility.

Value

This function returns an object of the same class of the input, i.e. an array or a BIMETS time series.

# array lag 3
out_movavg=MOVAVG(inputArray,3)
print(out_movavg)

# ts lag 4 centered with missings
ts1=TSERIES(inputArray,START=c(2000,1),FREQ='A')
MOVTOT

Description
This function returns the moving sum of the elements of the input array or the input time series. The result is an object of the same class of the input, and its elements are the moving sum of length L of the input values. If the input is a time series, the DIRECTION of the moving sum, i.e. backward, forward or centered, can be provided. MTOT and MSUM are alias for MOVTOT and MOVSUM.

Usage

MOVSUM(x = NULL, L = NULL, DIRECTION = NULL, avoidCompliance = FALSE, ...)
MOVTOT(x = NULL, L = NULL, DIRECTION = NULL, avoidCompliance = FALSE, ...)

Arguments

x
Input numerical array or time series that must satisfy the compliance control check defined in is.bimets.

L
Length of the sum. Must be a positive integer.

DIRECTION
if x is a time series, given y as output and x as input:
AHEAD: the output observation value in index n will be y[n] = sum(x[n],x[n+1],...,x[n+L-1]).
CENTER: the output observation value in index n will be y[n] = sum(x[n-trunc(L/2)],...x[n],x[n+1],...,x[n+trunc(L/2)]).
NULL o BACK: (default) the output observation value in index n will be y[n] = sum(x[n+1-L],...,x[n-1],x[n]).

avoidCompliance
If TRUE, compliance control check of input time series will be skipped. See is.bimets

Value
This function returns an object of the same class of the input, i.e. an array or a BIMETS time series.

MULTMATRIX

Compute the multiplier matrix of a BIMETS model object

Description

This function computes the matrix of both impact and interim multipliers, for a selected set of endogenous variables (i.e. TARGET) with respect to a selected set of exogenous variables (i.e. INSTRUMENT), by subtracting the results from different simulations in each period of the provided time range (i.e. TSRANGE). The simulation algorithms are the same as those used for the SIMULATE operation.

The MULTMATRIX procedure is articulated as follows:

1- simultaneous simulations are done;

2- the first simulation establishes the base line solution (without shocks);
3- the other simulations are done with shocks applied to each of the INSTRUMENT one at a time for every period in TS RANGE;

4- each simulation follows the defaults described in the SIMULATE help page, but has to be STATIC for the IMPACT multipliers and DYNAMIC for INTERIM multipliers;

5- given the shock amount MM_SHOCK as a very small positive number, derivatives are computed by subtracting the base line solution of the TARGET from the shocked solution, then dividing by the value of the base line INSTRUMENT time the MM_SHOCK.

The IMPACT multipliers measure the effects of impulse exogenous changes on the endogenous variables in the same time period. They can be defined as partial derivatives of each current endogenous variable with respect to each current exogenous variable, all other exogenous variable being kept constant.

Given $Y(t)$ an endogenous variable at time $t$ and $X(t)$ an exogenous variable at time $t$ the impact multiplier $m(Y, X, t)$ is defined as $m(Y, X, t) = \partial Y(t)/\partial X(t)$ and can be approximated by $m(Y, X, t) \approx (Y_{shocked}(t) - Y(t))/(X_{shocked}(t) - X(t))$, with $Y_{shocked}(t)$ the values for the simulated endogenous variable $Y$ at time $t$ when $X(t)$ is shocked to $X_{shocked}(t) = X(t)(1 + MM\_SHOCK)$

The INTERIM or delay-r multipliers measure the delay-r effects of impulse exogenous changes on the endogenous variables in the same time period. The delay-r multipliers of the endogenous variable $Y$ with respect to the exogenous variable $X$ related to a dynamic simulation from time $t$ to time $t+r$ can be defined as the partial derivative of the current endogenous variable $Y$ at time $t+r$ with respect to the exogenous variable $X$ at time $t$, all other exogenous variable being kept constant.

Given $Y(t + r)$ an endogenous variable at time $t + r$ and $X(t)$ an exogenous variable at time $t$ the impact interim or delay-r multiplier $m(Y, X, t, r)$ is defined as $m(Y, X, t, r) = \partial Y(t + r)/\partial X(t)$ and can be approximated by $m(Y, X, t, r) \approx (Y_{shocked}(t + r) - Y(t + r))/(X_{shocked}(t) - X(t))$, with $Y_{shocked}(t + r)$ the values for the simulated endogenous variable $Y$ at time $t + r$ when $X(t)$ is shocked to $X_{shocked}(t) = X(t)(1 + MM\_SHOCK)$

Users can also declare an endogenous variable as the INSTRUMENT variable. In this case, the constant adjustment (see SIMULATE) related to the provided endogenous variable will be used as the INSTRUMENT exogenous variable (see example):

**Usage**

```r
MULTMATRIX(model=NULL,
...)
```
**Arguments**

model

The BIMETS model object for which the multipliers matrix has to be calculated. The operation requires that all the behavioral items in the model have been previously estimated: all the behavioral coefficients (i.e. the estimation coefficients and the autoregression coefficients for the errors, if any) must be numerically defined in the model object. (see also `ESTIMATE`)

Other options to be sent to the underlying `SIMULATE` operation, e.g.:

**TSRANGE**: the time range of the multiplier analysis, as a four dimensional numerical array, i.e. \( \text{TSRANGE}=c(\text{start\_year, start\_period, end\_year, end\_period}) \).

**simType**, the simulation type requested:
- DYNAMIC: the default, for interim multipliers. Whenever lagged endogenous variables are needed in the computations, the simulated values of the endogenous variables evaluated in the previous time periods are used;
- STATIC: for impact multiplier. Rather than the simulated values, the actual historical values are used whenever lagged endogenous variables are needed in the computations;

**TARGET**: a character array built with the names of the endogenous variables for which the multipliers are requested;

**INSTRUMENT**: a character array with the names of the exogenous variables with respect to which the multipliers are computed. Users can also declare an endogenous variable as the INSTRUMENT variable: in this case the constant adjustment (see `SIMULATE`) related to the provided endogenous variable will be used as the instrument exogenous variable (see example);

**MM_SHOCK**: the shock value added to variables in the derivative calculation. The default value is \( 0.00001 \) times the value of the exogenous variable (see also `MULTMATRIX`);

**simConvergence**: the percentage convergence value requested for the iterative process, that stops when the percentage difference of all the feedback variables between iterations is less than `simConvergence` in absolute value;

**simIterLimit**: the value representing the maximum number of iterations to be performed. The iterative procedure will stop when `simIterLimit` is reached or the feedback variables satisfy the `simConvergence` criterion;

**ZeroErrorAC**: if TRUE it zeroes out all the autoregressive terms, if any, in the behavioral equations;

**Exogenize**: a named list that specifies the endogenous variables to be exogenized. During the simulation, in the specified time range the exogenized endogenous variables will be assigned their historical values. The list names are
the names of the endogenous variables to be exogenized; each element of this list contains the time range of the exogenization for the related endogenous variable, in the form of a 4-dimensional integer array, i.e. start_year, start_period, end_year, end_period. An element of the list can also be assigned TRUE: in this case the related endogenous variable will be exogenized in the whole simulation TSRANGE (see SIMULATE);

**ConstantAdjustment**: a named list that specifies the constant adjustments (i.e. add factors) to be added to the selected equations of the model. Each constant adjustment can be see as a new exogenous variable added to the equation of the specified endogenous variable. The list names are the names of the endogenous variables involved; each element of this is list contains the time series to be added to the equation of the related endogenous variable. Each provided time series must be compliant with the compliance control check defined in `is.bimets` (see SIMULATE);

**verbose**: if TRUE some verbose output will be activated. Moreover the values of all endogenous variables will be printed out during each iteration for all time periods in the simulation TSRANGE;

**quietly**: if TRUE the MULTMATRIX operation will be executed quietly.

**Value**

This function will add a new element named MultiplierMatrix into the output BIMETS model object.

The new MultiplierMatrix element is a (NumPeriods * Nendogenous) X (NumPeriods * Nexogenous) matrix, with NumPeriods as the number of periods specified in the TSRANGE, Nendogenous the count of the endogenous variables in the TARGET array and Nexogenous the count of the exogenous variables in the INSTRUMENT array.

The arguments passed to the function call during the latest MULTMATRIX() run will be inserted into the `__SIM_PARAMETERS__` element of the model simulation list (see SIMULATE); that can be useful in order to replicate the multiplier matrix results.

Row and column names in the output multiplier matrix identify the variables and the periods involved in the derivative solution, with the syntax VARIABLE_PERIOD (see example).

NAMELIST

Named List of Time Series

Description

In the case of strings input, this function returns a string array built with the input strings. In the case of time series input, this function returns a list built with the input time series; the output list names will be the variable names passed as arguments.

Usage

NAMELIST(...)

Arguments

... List of strings or list of time series. In the case of a list of strings, if an input string is not eligible to be a variable name, e.g. a string composed only with numbers, or with special characters, a warning will be thrown and a message will describe the required change made to the input string in order to make it eligible to be a variable name (see example).

Value

In the case of strings as input, this function returns a string array built with the input strings. In the case of time series as input, this function returns a list built with the input time series; the output list names will be the variable names passed as arguments.

<table>
<thead>
<tr>
<th>Count Elements</th>
</tr>
</thead>
</table>

**Description**

This function returns a numerical array built with the length of each input argument. Input arguments can be numerical or time series. Input arguments can also be string variables.

**Usage**

NOELS(...)  

**Arguments**

...  

List of input arguments. This function accepts input of class numerical, character, or BIMETS time series. Character arguments are exclusive: if an argument is of class character, all other arguments must be of class character.

**Value**

This function returns an array of class c().
`normalizeYP`  Normalize Year-Period Array

**Description**

This function normalizes a numerical array `c(YEAR,PERIOD)`, given a frequency `f` and `PERIOD>=f`. E.g. `normalizeYP(c(2000,15),12) = c(2001,3)`

**Usage**

`normalizeYP(x = NULL, f = NULL)`

**Arguments**

- `x` Input numerical array `c(YEAR,PERIOD)`
- `f` Frequency of normalization. Must be a positive integer.

**Value**

This function returns a numerical array `c(YEAR,PERIOD)`
NUMPERIOD

**Description**

This function returns the number of time periods that lie between the provided starting period \( x_1 = c(YEAR1, PRD1) \) and the provided ending period \( x_2 = c(YEAR2, PRD2) \), given a frequency \( f \).

**Usage**

\[
\text{NUMPERIOD}(x_1, x_2, f = \text{NULL})
\]

**Arguments**

- \( x_1 \): Starting period specified as a numerical array \( c(YEAR,PRD) \)
- \( x_2 \): Ending period specified as a numerical array \( c(YEAR,PRD) \)
- \( f \): Frequency over the year. Must be a positive integer.

**Value**

This function returns an integer of class numeric.

**See Also**

- `normalizeYP`
- `frequency`
- `GETDATE`
- `LOCS`
- `NAMELIST`

**Examples**

\[
\# f=5, c(3,4) - c(2,3) = 6 \text{ periods}
\]

\[
\text{print(NUMPERIOD}(c(2,3),c(3,4),5))
\]
QUARTERLY Quarterly (Dis)Aggregation

Description
This function returns a quarterly (dis)aggregated time series, using as input an annual, semiannual, monthly or daily time series.

Usage
QUARTERLY(x = NULL, fun = NULL, avoidCompliance = FALSE, ...)

Arguments
x  Input time series that must satisfy the compliance control check defined in is.bimets.
fun  Only for daily or monthly input time series:
STOCK: the value of the input time series in the last observation of a quarter is assigned to the same quarter of the output time series.
NSTOCK: the value of the input time series in the last non-missing observation of a quarter is assigned to the same quarter of the output time series.
SUM: the sum of input observations in a quarter is assigned to the same quarter of the output time series.
NSUM: the sum of input non-missing observations in a quarter is assigned to the same quarter of the output time series.
AVE: the average of input observations in a quarter is assigned to the same quarter of the output time series.
NAVE: the average of input non-missing observations in a quarter is assigned to the same quarter of the output time series.

Only for semiannual or annual input time series:
NULL: (default) the output value of each quarterly observation is set equal to the value of the input observation the quarter belongs to (i.e. duplicated values over the period)
INTERP_END: the value of the input time series in a period is copied into the last quarter of the output time series that lies in the same period. Other values are calculated by linear interpolation.
INTERP_CENTER: the value of the input time series in a period is copied into the median quarter of the output time series that lies in the same period. Other values are calculated by linear interpolation.
INTERP_BEGIN: the value of the input time series in a period is copied into the first quarter of the output time series that lies in the same period. Other values are calculated by linear interpolation.

avoidCompliance  If TRUE, compliance control check of input time series will be skipped. See is.bimets
...

Backward compatibility.
Value
This function returns a quarterly BIMETS time series.

TABIT(QUARTERLY(ts1,fun='SUM'))

Description
The endogenous targeting of econometric models (a.k.a. "renormalization") consists of solving the model while interchanging the role of one or more endogenous variables with an equal number of exogenous variables.

This function determines the values for the INSTRUMENT exogenous variables which allow the objective TARGET endogenous variables to be achieved, with respect to the constraints given by the model MDL definition.

This is an approach to economic and monetary policy analysis, and is based on two assumptions:

1. there exists a desired level for a set of $n$ endogenous variables defined as TARGET;
2. there exists a set of $n$ exogenous variables defined as INSTRUMENT;

Given these premises, the endogenous targeting process consists in determining the values of the exogenous variables chosen as INSTRUMENT allowing us to achieve the desired values for the endogenous variables designated as TARGET. In other words the procedure allows users to exchange...
the role of exogenous and endogenous among a set of time series pairs.

Given a list of exogenous \texttt{INSTRUMENT} variables and a list of \texttt{TARGET} endogenous time series, the iterative procedure can be split into the following steps:

1. Computation of the multipliers matrix \texttt{MULTMAT} of the \texttt{TARGET} endogenous variables with respect to the \texttt{INSTRUMENT} exogenous variables (this is a square matrix by construction);

2. Solution of the linear system:

\[ V_{\text{exog}}(i + 1) = V_{\text{exog}}(i) + \texttt{MULTMAT}^{-1} \ast (V_{\text{endog}}(i) - \texttt{TARGET}), \]

where \( V_{\text{exog}}(i) \) are the exogenous variables in the \texttt{INSTRUMENT} list and \( V_{\text{endog}}(i) \) are the endogenous variables that have a related target in the \texttt{TARGET} list, given \( i \) the current iteration;

3. Simulation of the model with the new set of exogenous variables computed in step 2, then a convergence check by comparing the subset of endogenous variables arising from this simulation and the related time series in \texttt{TARGET} list. If the convergence condition is satisfied, or the maximum number of iterations is reached, the algorithm will stop, otherwise it will go back to step 1;

Users can also declare an endogenous variable as an \texttt{INSTRUMENT} variable. In this case, the constant adjustment related to the provided endogenous variable will be used as the instrument exogenous variable. This procedure is particularly suited for the automatic computation of the add-factors needed to fine tune the model into a baseline path and to improve the forecasting accuracy.

If the convergence condition is satisfied, the \texttt{RENORM} procedure will return the requested \texttt{INSTRUMENT} time series allowing us to achieve the desired values for the endogenous variables designated as \texttt{TARGET}.

\textbf{Usage}

\begin{verbatim}
RENORM(model=NULL,
       renormIterLimit=10,
       renormConvergence=10E-5,
       TSRANGE=NULL,
       TARGET=NULL,
       INSTRUMENT=NULL,
       ConstantAdjustment=NULL,
       quietly=FALSE,
       showWarnings=FALSE,
       tol=.Machine$double.eps,
       avoidCompliance=FALSE,
       ...)
\end{verbatim}
Arguments

model The BIMETS model object to be renormalized. The operation requires that all the behavioral coefficients in the model have been previously estimated: all the behavioral coefficients (i.e. the estimation coefficients and the autoregression coefficients for the errors, if any) must be numerically defined in the model object. (see also ESTIMATE)

renormIterLimit The value representing the maximum number of iterations to be performed. The iterative renormalization procedure will stop when renormIterLimit is reached or the TARGET variables satisfy the renormConvergence criterion;

renormConvergence The convergence value requested for the iterative renormalization process, that stops when the distance between each TARGET time series and the related simulated endogenous variable is less than the renormConvergence value;

TSRANGE The time range of the RENORM analysis, as a four dimensional numerical array, i.e. TSRANGE=c(start_year,start_period,end_year,end_period).

TARGET A named list that specifies the target endogenous variables. The list names are the names of the endogenous variables involved in the renormalization; each element of this list contains the time series of the target endogenous values; the time series must be compliant with the compliance control check defined in is.bimets (see examples);

INSTRUMENT A character array with the names of the exogenous variables involved in the renormalization. User can also declare an endogenous variable as INSTRUMENT variable: in this case the constant adjustment (see SIMULATE) related to the provided endogenous variable will be used as the instrument exogenous variable (see example);

ConstantAdjustment A named list that specifies the constant adjustments (i.e. add factors) to be added to the selected equations of the model (see also SIMULATE);

quietly If TRUE, information messages will be suppressed.

showWarnings If TRUE, a warning message will be shown if any input time series has missing values.

tol the tolerance for detecting linear dependencies in the columns of a matrix while an inversion is requested. The default is .Machine$double.eps.

avoidCompliance If TRUE, compliance control check of model time series will be skipped. See is.bimets

... Other options to be sent to the underlying MULTMATRIX operation, e.g.:

simType, the simulation type requested:
DYNAMIC: the default, for interim multipliers. Whenever lagged endogenous variables are needed in the computations, the simulated values of the endogenous variables evaluated in the previous time periods are used;
STATIC: for impact multiplier. Rather than the simulated values, the actual historical values are used whenever lagged endogenous variables are needed in the
computations; see also MULTMATRIX;

**simConvergence**: the percentage convergence value requested for the simulation process (see also SIMULATE);

**simIterLimit**: the value representing the maximum number of iterations to be performed in the simulation process (see also SIMULATE);

**ZeroErrorAC**: if TRUE it zeroes out all the autoregressive terms, if any, in the behavioral equations;

**Exogenize**: a named list that specifies the endogenous variables to be exogenized (see also SIMULATE);

**MM_SHOCK**: the value of the shocks added to variables in the derivative calculation of the multipliers. The default value is 0.00001 times the value of the exogenous variable (see also MULTMATRIX);

**Value**

This function will add a new element named `renorm` into the output BIMETS model object.

The new `renorm` element is a named R list that contains the following elements:

- **INSTRUMENT**: a named R list that contains the time series of the INSTRUMENT exogenous variables which allow the objective TARGET endogenous variables to be achieved. The names of this list are the names of the related exogenous variables. This element is populated only if the convergence is reached. Users can also declare an endogenous variable as INSTRUMENT variable: in this case the constant adjustment (see SIMULATE) related to the provided endogenous variable will be used as the instrument exogenous variable. In this case, this INSTRUMENT output list will contains also the time series of the constant adjustment related to the provided endogenous variable (see example)

- **TARGET**: a named R list built with the time series of the achieved TARGET endogenous variables. The names of this list are the names of the related endogenous variables the time series belong to;

- **unConvergedTARGET**: the names array of the endogenous TARGET variables that failed the convergence. This element is populated only if the convergence has not been reached;

- **modelData**: the whole model input dataset wherein the INSTRUMENT exogenous variables have been modified accordingly to the RENORM output time series. This can be useful in order to verify that the model fed with the proper INSTRUMENT exogenous variable produces the desired TARGET endogenous values. This element is populated only if the convergence is reached;

- **ConstantAdjustment**: the constant adjustment input list provided during the function call, if any, wherein the constant adjustment related to a INSTRUMENT endogenous variables have been modified accordingly to the RENORM output time series. This can be usefull in order to verify that the model fed with the proper INSTRUMENT exogenous variable and with the proper ConstantAdjustment (if any) produces the desired TARGET endogenous values. This element is populated only if the convergence is reached;

- **__RENORM_PARAMETERS__**: a named R list that contains the arguments passed to the function call during the latest RENORM() run, e.g. TSRANGE, renormIterLimit, INSTRUMENT, TARGET,
etc.: that can be useful in order to replicate the renorm results.

**SEMIANNUAL**

**Semiannual (Dis)Aggregation**

**Description**

This function returns a semi-annual (dis)aggregated time series, by using as input an annual, quarterly, monthly or daily time series.

**Usage**

SEMIANNUAL(x = NULL, fun = NULL, avoidCompliance = FALSE, ...)

**Arguments**

- **x**
  - Input time series that must satisfy the compliance control check defined in `is.bimets`.

- **fun**
  - Only for daily or monthly or quarterly input time series:
    - **STOCK**: the value of the input time series in the last observation of a half-year is assigned to the same half-year of the output time series.
    - **NSTOCK**: the value of the input time series in the last non-missing observation of a half-year is assigned to the same half-year of the output time series.
    - **SUM**: the sum of input observations in a half-year is assigned to the same half-year of the output time series.
    - **NSUM**: the sum of input non-missing observations in a half-year is assigned to the same half-year of the output time series.
    - **AVE**: the average of input observations in a half-year is assigned to the same half-year of the output time series.
    - **NAVE**: the average of input non-missing observations in a half-year is assigned to the same half-year of the output time series.
  - Only for annual input time series:
    - **NULL**: (default) the output value of each half-year observation is set equal to the value of the input observation the half-year belongs to (i.e. duplicated values over the period)
    - **INTERP_END**: the value of the input time series in a period is copied into the last half-year of the output time series that lies in the same period. Other values are calculated by linear interpolation.
    - **INTERP_CENTER**: the value of the input time series in a period is copied into
the median half-year of the output time series that lies in the same period. Other values are calculated by linear interpolation.

**INTERP_BEGIN:** the value of the input time series in a period is copied into the first half-year of the output time series that lies in the same period. Other values are calculated by linear interpolation.

**avoidCompliance**
- If TRUE, compliance control check of input time series will be skipped. See `is.bimets`
- Backward compatibility.

**Value**

This function returns a semiannual BIMETS time series.

**See Also**

- `ANNUAL`
- `QUARTERLY`
- `MONTHLY`
- `DAILY`

**Examples**

```r
#TS QUARTERLY TO SEMIANNUAL
n=14
xArr=(n:0)
ts1=TSERIES(xArr,START=c(2000,1),FREQ='Q')
print(SEMIANNUAL(ts1,fun='NAVE'))

#TS ANNUAL TO SEMIANNUAL
ts1=TSERIES((1:10),START=c(2000,1),FREQ=1)
print(SEMIANNUAL(ts1,fun='INTERP_END'))
```

**Description**

The simulation of an econometric model basically consists in solving the system of the equations describing the model for each time period in the specified time interval. Since the equations may not be linear in the variables, and since the graph derived from the incidence matrix may be cyclic, the usual methods based on linear algebra are not applicable, and the simulation must be solved by using an iterative algorithm.

BIMETS simulation capabilities support:
- **Static simulations**: a static multiple equation simulation, in which the historical values for the lagged endogenous variables are used in the solutions of subsequent periods;

- **Dynamic simulations**: a dynamic simulation, in which the simulated values for the lagged endogenous variables are used in the solutions of subsequent periods;

- **Residuals check**: a single period, single equation simulation; simulated time series in output are just the computation of the RHS (right-hand-side) of their equation, by using the historical values of the involved time series and by accounting for error autocorrelation and PDLs, if any;

- **Forecast simulations**: similar to dynamic simulation, but during the initialization of the iterative algorithm the starting values of endogenous variables in a period are set equal to the simulated values of the previous period. This allows the simulation of future endogenous observations, i.e. the forecast;

- **Partial or total exogenization of endogenous variables**: in the provided time interval (i.e. partial exog.) or in the whole simulation time range (i.e. total exog.), the values of the selected endogenous variables can be definitely set equal to their historical values, by excluding their equations from the iterative algorithm of simulation;

- **Constant adjustment of endogenous variables (add-factors)**: adds another exogenous time series - the "constant adjustment" - in the equation of the selected endogenous variables;

In details, the generic model suitable for simulation in BIMETS can be written as:

\[
\begin{align*}
y_1 &= f_1(\bar{x}, \bar{y}) + z_1 \\
& \vdots \\
y_n &= f_n(\bar{x}, \bar{y}) + z_n
\end{align*}
\]

being:

\[n\] the number of equations in the model;
\[
\bar{y} = [y_1, \ldots, y_n]\] the \(n\)-dimensional vector of the endogenous variables;
\[
\bar{x} = [x_1, \ldots, x_m]\] the \(m\)-dimensional vector of the exogenous variables;
\[
f_i(\ldots), i = 1..n\] any kind of functional expression able to be written by using the MDL syntax;

As described later on, a modified Gauss-Seidel iterative algorithm can solve the system of equations. The convergence properties may vary depending on the model specifications. In some conditions, the algorithm may not converge for a specific model or a specific set of data.

A convergence criterion and a maximum number of iterations to be performed are provided by default. Users can change these criteria by using the `simConvergence` and `simIterLimit` arguments of the `SIMULATE()` function.

The general conceptual scheme of the simulation process (for each time period) is the following:

1. initialize the solution for the current simulation period;
2. iteratively solve the system of equations;
3. save the solution, if any;

Step 2 means that for each iteration you will need to:

2.1 update the values of the current endogenous variables;
2.2 verify that the convergence criterion is satisfied or that the maximum number of allowed iterations has been reached;

The initial solution for the iterative process (step 1) can be given alternatively by:

- the historical value of the endogenous variables for the current simulation period (the default);
- the simulated value of the endogenous variables from the previous simulation period (this alternative is driven by the simType='FORECAST' argument of the SIMULATE() function);

In the "dynamic" simulations (i.e. simulations performed by using either the default simType='DYNAMIC' or the simType='FORECAST'), whenever lagged endogenous variables are needed in the computation, the simulated values of the endogenous variables \( \bar{y} \) assessed in the previous time periods are used. In this case, the results of the simulation in a given time period depends on the results of the simulation in the previous time periods. This kind of simulation is defined as "multiple equation, multiple period".

As an alternative, the actual historical values can be used in the "static" simulations (i.e. simulations performed by using simType='STATIC') rather than simulated values whenever lagged endogenous variables are needed in the computations. In this case, the results of the simulation in a given time period does not depend on the results of the simulation in the previous time periods. This kind of simulation is defined as "multiple equation, single period".

The last simulation type available is the residual check (simType='RESCHECK'). With this option a "single equation, single period" simulation is performed. In this case no iteration must be carried out. The endogenous variables are assessed for each single time period through the use of historical values for each variable on the right-hand side of the equation, for both lagged and current periods. This kind of simulation is very helpful for debugging and checking the logical coherence of the equations and the data, and can be used as a simple tool to compute the add-factors.

The debugging of the logical coherence of the model-equation and the data is carried out by means of a procedure called "Residual Check".

It consists in the following steps:

1. add another exogenous variable - the constant adjustment - to every equation of the model, both behavioral and technical identity (i.e. by using the ConstantAdjustment argument of the SIMULATE() function);
2. fill in with the estimated residuals all the constant adjustments for the behavioral equations;
3. fill in with zeroes the constant adjustments for the technical identities;
4. perform a simulation of the model with the simType='RESCHECK' option;
5. compute the difference between the historical and the simulated values for all the endogenous variables;
6. check whether all the differences assessed in step 5 are zero in the whole time range;
If a perfect tracking of the history is obtained then the equations have been written coherently with the data, otherwise a simulated equation not tracking the historical values is an unambiguous symptom of data inconsistent with the model definition.

Aside from the residual check, the add-factors constitute an important tool to significantly improve the accuracy of forecasts made through an econometric model. Considering the following model:

\[
y_1 = f_1(\bar{x}, \bar{y}) + z_1
\]

...\[
y_n = f_n(\bar{x}, \bar{y}) + z_n
\]

the add-factors \( \bar{z} = [z_1, ..., z_n] \) can be interpreted as estimates of the future values of the disturbance terms or, alternatively, as adjustments of the intercepts in each equation. These add-factors round out the forecasts, by summarizing the effects of all the systematic factors not included in the model. One choice for the computation of the add-factors is given by past estimation residuals and past forecast errors or by an average of these errors. This consideration suggests an easy way of computing the add-factors:

1. add the constant adjustments to every equation of the model, both behavioral and technical identity;
2. fill in with zeroes all the constant adjustments;
3. solve the model, with the simType='RESCHECK' option, in a time interval including some periods beyond the estimation sample;
4. compute the difference between the historical and the simulated values for each the endogenous variables;
5. average, or process in a suitable way, the difference arising from point 4 in the time periods beyond the estimation sample to compute the constant value to be used as an add-factor in the following forecasting exercises;

Please note that in case of equation that presents an LHS function the add-factor will be added before the application of the inverse function, i.e. during the simulation the following:

\[
g_1(y_1) = f_1(\bar{x}, \bar{y}) + z_1
\]

...\[
g_n(y_n) = f_n(\bar{x}, \bar{y}) + z_n
\]

will be solved as:

\[
y_1 = g_1^{-1}(f_1(\bar{x}, \bar{y}) + z_1)
\]

...\[
y_n = g_n^{-1}(f_n(\bar{x}, \bar{y}) + z_n)
\]

If a linear dependence from the simulated endogenous and the add-factor is preferred, users can manually insert an auxiliary equation \( w_i \) into the model definition, e.g. the following:

\[
g_i(y_i) = f_i(\bar{x}, \bar{y})
\]
can be replaced by:

\[ w_i = f_i(\bar{x}, \bar{y}) \]
\[ y_i = g_i^{-1}(w_i) \]

During the simulation, the add-factors will be applied as in the following:

\[ w_i = f_i(\bar{x}, \bar{y}) + v_i \]
\[ y_i = g_i^{-1}(w_i) + z_i \]

given \( v_i, z_i \) as add-factors and the linear dependence from \( z_i \) and \( y_i \).

**THE OPTIMAL REORDERING**

In fact, the simulation process takes advantage of an appropriate ordering of the equations to increase the performances by iteratively solving only one subset of equations, while the others are solved straightforwardly. "...a different ordering of the equations can substantially affect the speed of convergence of the algorithm; indeed some orderings may produce divergence. The less feedback there is, the better the chances for fast convergence..." - Don, Gallo - Solving large sparse systems of equations in econometric models - Journal of Forecasting 1987.

The `LOAD_MODEL` function builds the incidence matrix of the model, then defines the proper equation reordering. The incidence matrix is built from the equations of the model; it is a square matrix in which each row and each column represents an endogenous variable. If the \((i,j)\) element is equal to 1 then in the model definition the current value of the endogenous variable referred by the \(i\)-row depends directly from the current value of the endogenous variable referred by the \(j\)-column.

In econometric models, the incidence matrix is usually very sparse. Only a few of the total set of endogenous variables are used in each equation. In this situation, ordering the equation in a certain sequence will lead to a sensible reduction of the number of iterations needed to achieve convergence. Reordering the equations is equivalent to rearranging rows and columns of the incidence matrix. In this way the incidence matrix might be made lower triangular for a subset of the equations. For this subset, an endogenous variable determined in a specific equation has no incidence in any equation above it, although the same variable might have incidence in equations below it. Such a subset of equations is called recursive. Recursive systems are easy to solve. It is only necessary to solve each equation once if this is done in the right order. On the other hand, it is unlikely for the whole model to be recursive. Indeed the incidence graph is often cyclic, as in the Klein’s model that presents the following circular dependencies in the incidence matrix: \( cn \leftarrow w1 \leftarrow y \leftarrow cn \)

For a subset of the equations, some 1’s will occur in the upper triangle of the incidence matrix for all possible orderings. Such subset of equations is called **simultaneous**. In order to be able to solve the endogenous variables in the simultaneous block of equations, an iterative algorithm has to be used. Nevertheless, the equations in the simultaneous block may be ordered so that the pattern of the 1’s in the upper triangle of the incidence matrix forms a spike. The variables corresponding to the 1’s in the upper triangle are called **feedback** variables.
A qualitative graphical example of an ordered incidence matrix is given in the following figure. The white areas are all 0’s, the gray areas contain 0’s and 1’s. The 1’s in the light gray areas refer to variables already evaluated in previous blocks, therefore they are known terms within the block. The 1’s in the dark gray areas refer to variables evaluated within the block.

The final pattern of an incidence matrix after the equation reordering generally features three blocks:

1. a recursive block (the pre-recursive block);
2. a simultaneous block;
3. another recursive block (the post-recursive block);

As said, the pre-recursive and the post-recursive blocks are lower triangular. Therefore the corresponding equations are solvable with a cascade substitution with no iteration. Just the simultaneous equations set needs an iterative algorithm to be solved. It is important to say that the convergence criterion may also be applied to these variables only: when the feedback variables converge, the rest of the simultaneous variables also do.

BIMETS builds and analyzes the incidence matrix of the model, and then it orders the equations in pre-recursive, post-recursive and simultaneous blocks. The simultaneous block is then analyzed in order to find a minimal set of feedback variables. This last problem is known to be NP-complete (Ref: Garey, Johnson - Computers and Intractability: a Guide to the Theory of NP-completeness - San Francisco, Freeman 1979).

The optimal reordering of the model equations is programmatically achieved through the use of an iterative algorithm applied to the incidence matrix that can produce 4 ordered lists of endogenous variables:

1. vpre is the ordered list containing the names of the endogenous pre-recursive variables to be sequentially computed (by using their EQ> definition in the MDL) before the simulation iterative algorithm takes place;
2. vsim is the ordered list containing the names of the endogenous variables to be sequentially
computed during each iteration of the simulation iterative algorithm;
3. \texttt{vfeed} is the list containing the names of the endogenous feedback variables;
4. \texttt{vpost} is the ordered list containing the names of the endogenous post-recursive variables to be
   sequentially computed once the simulation iterative algorithm has converged;

If equations are reordered, the previous conceptual scheme is modified as follow:

- initialize the solution for the current simulation period;
- compute the pre-recursive equations (i.e. the equation of the endogenous variables in the \texttt{vpre}
  ordered list);
- iteratively compute the system of simultaneous equations (i.e. the equation of the endogenous
  variables in the \texttt{vsim} ordered list); for each iteration update the values of the current endogenous
  variables and verify that the convergence criterion is satisfied on the feedback variables or that the
  maximum number of iterations has been reached;
- compute the post-recursive equations (i.e. the equation of the endogenous variables in the \texttt{vpost}
  ordered list);
- save the solutions;

Given $y_{i,k}$ the value of the $i$-endogenous variable in the simultaneous block at the iteration $k$, with
$i$ the position of the equation in a reordered model, the modified Gauss-Seidel method simply takes
for the approximation of the endogenous variable $y_{i,k}$ the solution of the following:

$$y_{i,k} = f_i(x_1, \ldots, x_m, y_{1,k}, \ldots, y_{i-1,k}, y_{i,k-1}, \ldots, y_{n,k-1})$$

As said, the convergence is then tested at the end of each iteration on the feedback variables.

Newton's methods on a reordered model require the calculation of the Jacobian matrix on the feed-
back endogenous variables, i.e. at least $f+2$ iterations per simulation period, with $f$ as the number
of feedback variables. For large models (i.e. more than 30 feedback variables) if the overall re-
quired convergence is greater than $10^{-6}\%$ the speedup over the Gauss-Siebel method is small or
negative. Moreover the Gauss-Siebel method does not require a matrix inversion, therefore it is
more robust against algebraical and numerical issues. For small models both methods are fast on
modern computers.

The simulation of a non-trivial model, if computed by using the same data but on different hardware,
software or numerical libraries, produces numerical differences. Therefore a convergence criterion
smaller than $10^{-7}\%$ frequently leads to a local solution.

See \textit{Numerical methods for simulation and optimal control of large-scale macroeconomic models -

\textbf{Usage}

```R
SIMULATE(model=NULL,
         TSRANGE=NULL,
         simType='DYNAMIC',
         simConvergence=0.01,
         simIterLimit=20,
         ZeroErrorAC=FALSE,
```
BackFill=0,
Exogenize=NULL,
ConstantAdjustment=NULL,
verbose=FALSE,
verboseSincePeriod=0,
verboseVars=NULL,
MULTMATRIX=FALSE,
TARGET=NULL,
INSTRUMENT=NULL,
MM_SHOCK=0.00001,
quietly=FALSE,
RESCHECKeqList=NULL,
avoidCompliance=FALSE,
...}

Arguments

model The BIMETS model object to be simulated. The simulation requires that all
the behaviorals in the model have been previously estimated: all the behavioral
coefficients (i.e. the estimation coefficients and the autoregression coefficients
for the errors, if any) must be numerically defined in the model object. (see also
ESTIMATE)

TSRANGE The time range of the simulation, as a four dimensional numerical array,
i.e. TSRANGE=c(start_year,start_period,end_year,end_period).
simType The simulation type requested:
DYNAMIC: the default, whenever lagged endogenous variables are needed in
the computations, the simulated values of the endogenous variables evaluated in
the previous time periods are used;
STATIC: rather than the simulated values, the actual historical values are used
whenever lagged endogenous variables are needed in the computations;
FORECAST: similar to the 'DYNAMIC' option, but the initial solutions for the
iterative process are given by the simulated values of the endogenous variables
in the previous period. In this case there is no need for historical values of the
endogenous variables in the whole provided TSRANGE;
RESCHECK: in this case there is no iteration to carry out. The endogenous
variables are evaluated for each single time period by using the historical values
for all the variables on the right-hand side of the equation, both lagged and
current period;
simConvergence The percentage convergence value requested for the iterative process, that stops
when the percentage difference of all the feedback variables between iterations
is less than simConvergence in absolute value;
simIterLimit The value representing the maximum number of iterations to be performed. The
iterative procedure will stop when simIterLimit is reached or the feedback
variables satisfy the simConvergence criterion;
ZeroErrorAC If TRUE it zeroes out all the autoregressive terms, if any, in the behavioral equa-
tions;
BackFill
Defined as an integer, it is the length of historical data prior to the simulation TSRANGE to be saved along with the solutions.

Exogenize
A named list that specifies the endogenous variables to be exogenized. During the simulation and inside the provided time range, the exogenized endogenous variables will be assigned to their historical values. List names must be the names of the endogenous variables to be exogenized; each element of this list contains the time range of the exogenization for the related endogenous variable, in the form of a 4-dimensional integer array, i.e. start_year, start_period, end_year, end_period. A list element can also be assigned TRUE: in this case the related endogenous variable will be exogenized in the whole simulation TSRANGE (see examples);

ConstantAdjustment
A named list that specifies the constant adjustments (i.e. add factors) to be added to the selected equations of the model. Each constant adjustment can be see as a new exogenous variable added to the equation of the specified endogenous variable. The list names are the names of the involved endogenous variables; each element of this list contains the time series to be added to the equation of the related endogenous variable. Each provided time series must verify the compliance control check defined in is.bimets (see examples);

verbose
If TRUE some verbose output will be activated. Moreover the values of all endogenous variables will be printed out during each iteration and for all time periods inside the simulation TSRANGE;

verboseSincePeriod
An integer that activate the verbose output, during the iterative process, only after the provided number of simulation periods;

verboseVars
A character array with the names of the endogenous variables for which the verbose output will be activated in the iterative process;

MULTMATRIX
It is TRUE when the simulation is a vectorial simulation requested by a MULTMATRIX operation;

TARGET
A character array built with the names of the endogenous variables for which the multipliers are requested (see MULTMATRIX);

INSTRUMENT
A character array built with the names of the exogenous variables with respect to which the multipliers are evaluated. Users can also declare an endogenous variable as INSTRUMENT variable: in this case the constant adjustment (see SIMULATE) related to the provided endogenous variable will be used as the instrument exogenous variable (see MULTMATRIX);

MM_SHOCK
The value of the shocks added to variables in the derivative calculation of the multipliers. The default value is 0.00001 times the value of the exogenous variable (see MULTMATRIX);

quietly
If TRUE, information messages will be suppressed.

RESCHECKeqList
If simType=RESCHECK, by using this arguments users can select a subset of target endogenous variables: the simulation will be performed only for the selected variables. It must be provided as an array of endogenous names, e.g. c(’endo1’,’endo2’,...).
avoidCompliance
If TRUE, compliance control check of model time series will be skipped. See is.bimets
...
Backward compatibility.

Value
This function will add a new element named simulation into the output BIMETS model object.

The new simulation element is a named R list; the names of the simulation list are the names of the endogenous variables of the model; each element of the simulation list contains the simulated time series of the related endogenous variable (see examples).

The simulation list also contains the '___SIM_PARAMETERS___' element that contains the arguments passed to the function call during the latest SIMULATE() run, e.g. TSRANGE, symType, simConvergence, symIterLimit, Exogenize, etc.: that can be useful in order to replicate the simulation results.

summary.BIMETS_MODEL

Print basic information about a BIMETS model
Description

This function prints basic information about a BIMETS model, e.g. behaviorals and identities count, coefficients count, the presence of estimated coefficients or simulated time series.

Usage

```r
## S3 method for class 'BIMETS_MODEL'
summary(object,...)
## S3 method for class 'BIMETS_MODEL'
print(x,...)
```

Arguments

- `object`: A BIMET model.
- `x`: A BIMET model.
- `...`: Arguments list for the generic method.

Value

This function prints basic information about a BIMETS model, i.e.:

- the name of the model;
- the behaviorals count;
- the identities count;
- the coefficients count;
- the check for the compliance of the model data;
- the check for the coefficients definition in all the behaviorals;
- the check for the definition of a simulated time series for each related endogenous variable of the model;

**TABIT**

**Print Time Series Data**

### Description

This function prints, in an human-readable format, the content of a list of time series. Time series can be subsetted with the projection argument `TSRANGE`.

### Usage

```r
TABIT(...,
    TSRANGE=NULL,
    digits=getOption('digits'),
    avoidCompliance=FALSE)
```

### Arguments

- `...`: Input list of time series that must satisfy the compliance control check defined in `is.bimets`.
- `TSRANGE`: Optional date range of data presentation. `TSRANGE` must be specified as a numerical array composed by starting year, starting period, ending year and ending period of projection, i.e. `TSRANGE=c(START_YEAR,START_PERIOD,END_YEAR,END_PERIOD)`.
- `digits`: Controls the number of digits to print out. Valid values are 1 to 22 with a default of 7.
- `avoidCompliance`: If `TRUE`, compliance control check of input time series will be skipped. See `is.bimets`

### Value

This function prints out time series data and returns a `NULL` value.

CUMSUM

Examples

```r
#random TS
n=10
xArr=rnorm(n)
ts1=TSERIES(xArr,START=c(2000,1),FREQ='A')
TABIT(ts1,TSDETA(ts1,1,1),TSDETA(ts1,1,2),TSDETA(ts1,1,3))
```

---

**TSDELTALOG**

*Time Series Lag Logarithmic Differences*

Description

This function returns the L-lag logarithmic differences of the input time series.

Usage

```r
TSDELTALOG(x = NULL, L = 1, avoidCompliance = FALSE, ...)
```

Arguments

`x` Input time series that must satisfy the compliance control check defined in `is.bimets`.

`L` Lag.

`avoidCompliance` If TRUE, compliance control check of input time series will be skipped. See `is.bimets`

... Backward compatibility.
Value

This function returns a BIMETS time series.

TSDELTA
TSLAG
MOVAVG
INTS
CUMSUM

Examples

```r
#random TS
n=10
ts1=TSERIES(1:n,START=c(2000,1),FREQ='A')
TABIT(ts1,TSDELTA(ts1,1))
```

TSDELTA

Time Series Percentage Lag Differences (Delta Percentage)

Description

This function returns the 0-order, L-lag percentage differences of the input time series. If the input time series frequency is a multiple of the L lag argument, then it is possible to set the argument `ANNUALIZE=TRUE` in order to have the percent changes returned at annual rates, i.e. raised to power of frequency/L.

Usage

```
TSDELTA(x = NULL, L = 1, ANNUALIZE = FALSE, avoidCompliance = FALSE, ...)
```

Arguments

- **x**: Input time series that must satisfy the compliance control check defined in `is.bimets`.
- **L**: Lag.
- **ANNUALIZE**: If TRUE the percent changes are returned as annual rates, i.e. raised to the power of frequency/L.
- **avoidCompliance**: If TRUE, compliance control check of input time series will be skipped. See `is.bimets`
- **...**: Backward compatibility.
TSERIES

Value

This function returns a BIMETS time series.

#TS 366
tr1=TSERIES(seq(1,length=10,by=-0.001),START=c(2000,1),FREQ=366)
TABIT(tr1,TSDELTAP(tr1,1,ANNUALIZE=TRUE))

TSERIES

Create a Time Series

Description

This function returns a time series that is compliant with BIMETS compliance control defined in
is.bimets. Users can provide observation values, frequency and the starting period. Moreover
users can provide metadata information that will be stored into the time series object as attributes.

TIMESERIES is an alias for TSERIES.

Usage

TIMESERIES(..., START = c(2000,1), FREQ = 1,
    SOURCE = NULL, TITLE = NULL, UNITS = NULL, SCALEFAC = 0,
    class=NULL, avoidCompliance = FALSE)

TSERIES(..., START = c(2000,1), FREQ = 1,
    SOURCE = NULL, TITLE = NULL, UNITS = NULL, SCALEFAC = 0,
    class=NULL, avoidCompliance = FALSE)
Arguments

List of values to be inserted into the output time series. This function accepts arguments of class \texttt{ts()} and \texttt{xts()}, that must be BIMETS compliant as defined in \texttt{is.bimets}, and also accepts numerical arrays. Please note that for daily and weekly time series, as in the default R time series class \texttt{ts()}, this function will insert provided values always filling up to the 366th period in the daily case and up to the 53rd period in the weekly case. (see examples)

\textbf{START}

This argument defines the start of the time series. Starting period can be specified as \texttt{c(YEAR,PERIOD)}, or as \texttt{Date()}, or as \texttt{yearmon()} if the frequency \texttt{FREQ}=12, or as \texttt{yearqtr()} if the frequency \texttt{FREQ}=4. Please note that the time series must lie in the years range 1800-2199.

\textbf{FREQ}

The frequency of the time series. Frequency can be \texttt{FREQ}=1,2,3,4,12,24,36,53, or 366. Frequency can also be defined by using the char 'A' or 'Y' for annual/yearly, 'S' for semiannual, 'Q' for quarterly, 'M' for monthly, 'W' for weekly, and 'D' for daily time series.

\textbf{SOURCE}

Set the metadata string that represents the source of the data. Metadata will be lost if the time series is transformed by any function that changes its values.

\textbf{TITLE}

Set the metadata string that represents the description of the data. Metadata will be lost if the time series is transformed by any function that changes its values.

\textbf{UNITS}

Set the metadata string that represents the unit of measure of the data. Metadata will be lost if the time series is transformed by any function that changes its values.

\textbf{SCALEFAC}

Set the metadata numerical value that represents the scale factor of the data. Users may eventually use this value in calculation. Metadata will be lost if the time series is transformed by any function that changes its values.

\textbf{class}

If \texttt{class='XTS'} this function will return a time series based on the \texttt{xts()} class. If \texttt{class='TS'} this function will return a time series based on the \texttt{ts()} class. If \texttt{class=NULL} (default) the output base class will be the one defined in the global BIMETS option 'BIMETS\_CONF\_CCT' (see BIMETS configuration). Please note that package functions only accept time series of the same class as the one defined in the global option 'BIMETS\_CONF\_CCT'. Users can change any global option directly in the code.

Please note that BIMETS package performs better with \texttt{class='TS'} or more generally with \texttt{BIMETS\_CONF\_CCT='TS'}

\textbf{avoidCompliance}

If \texttt{TRUE}, compliance control check of input time series will be skipped. See \texttt{is.bimets}

\textbf{Value}

This function returns a BIMETS time series that is compliant with the BIMETS compliance control defined in \texttt{is.bimets}.

### TSEXTEND

**Extend Time Series**

#### Description

This function extends the time series definition range by using a specified criteria. Values of time series extension are calculated by using the directives specified in the arguments `EXTMODE` and `FACTOR`.

#### Usage

```
TSEXTEND(x = NULL, BACKTO = NULL, UPTO = NULL, EXTMODE = "GROWTH", 
          FACTOR = NA, avoidCompliance = FALSE, ...) 
```

#### Arguments

- **x**
  - Input time series that must satisfy the compliance control check defined in `is.bimets`.

- **BACKTO**
  - Define the new start of the time series, that must be provided as `c(YEAR,PERIOD)`. It is possible to convert a `Date()`, or a `yearmon()`, or a `yearqtr()` to the related `c(YEAR,PERIOD)` by using the functions `date2yp`, `ym2yp`, and `yq2yp`.

- **UPTO**
  - Define the new end of the time series, that must be provided as `c(YEAR,PERIOD)`. It is possible to convert a `Date()`, or a `yearmon()`, or a `yearqtr()` to the related `c(YEAR,PERIOD)` by using the functions `date2yp`, `ym2yp`, and `yq2yp`.

- **EXTMODE**
  - It must be one of the following:
    - **MISSING**: extend the time series using missing values `NA`.
    - **ZERO**: extend the time series by using 0 (zero) values.
    - **CONSTANT**: extend the time series by using the closest non-missing observation.
    - **MEAN4**: extend the time series by using the mean of the closest four non-missing observations.
    - **LINEAR**: extend the time series by using the same increment of the closest couple of observations.
    - **QUADRATIC**: extend the time series by using the same quadratic increment of the closest eight observations.
    - **GROWTH**: extends the time series by using the closest growth rate.
    - **GROWTH4**: extend the time series by using the factor
      \[ r = \left( \frac{\text{mean}(x[-1:-4])}{\text{mean}(x[-5:-8])} \right)^{\frac{1}{4}} \]
    - **MYCONST**: extend the time series by using the value defined in `FACTOR`
    - **MYRATE**: extend the time series by using the increment defined in `FACTOR`
TSINFO

FACTOR
User-defined value used by some options of the EXTMODE argument.

avoidCompliance
If TRUE, compliance control check of input time series will be skipped. See is.bimets

... Backward compatibility.

Value
This function returns a BIMETS time series built by extending the input time series.

TSINFO

Get Time Series Info

Description
This function returns detailed information about the input time series list. Requested information is defined in the argument MODE.
Usage

```r
TSINFO(..., MODE = NULL, avoidCompliance=FALSE)
```

Arguments

- Input time series list. Each time series must satisfy the compliance control check defined in `is.bimets`.

- **MODE**

  - Select the information to be retrieved from the list of time series. `MODE` can be set to:

    - **STARTY**
      - the output will be a numerical array built with the starting year of each time series in the input list.
    - **ENDY**
      - the output will be a numerical array built with the ending year of each time series in the input list.
    - **STARTP**
      - the output will be a numerical array built with the starting period of each time series in the input list.
    - **ENDP**
      - the output will be a numerical array built with the ending period of each time series in the input list.
    - **START**
      - the output will be a numerical array built with the value \( x = \text{START\_YEAR} + \text{START\_PERIOD}/\text{FREQ} \) calculated on each time series in the input list, where \( \text{FREQ} \) is the time series frequency.
    - **END**
      - the output will be a numerical array built with the value \( x = \text{END\_YEAR} + \text{END\_PERIOD}/\text{FREQ} \) calculated on each time series in the input list.
    - **START2**
      - the output will be a numerical matrix. For each time series in the input list the matrix will have a row=\( c(\text{START\_YEAR}, \text{START\_PERIOD}) \) with related values.
    - **END2**
      - the output will be a numerical matrix. For each time series in the input list the matrix will have a row=\( c(\text{END\_YEAR}, \text{END\_PERIOD}) \) with related values.
    - **FREQ**
      - the output will be a numerical array built with the frequency of each time series in the input list.
    - **FACTOR**
      - the output will be a numerical array built with the SCALEFAC metadata value of each time series in the input list.
    - **UNITS**
      - the output will be a string array built with the UNITS metadata string of each time series in the input list.
    - **TITLE**
      - the output will be a string array built with the TITLE metadata string of each time series in the input list.
    - **SOURCE**
      - the output will be a string array built with the SOURCE metadata string of each time series in the input list.

- **avoidCompliance**

  - If `TRUE`, compliance control check of input time series will be skipped. See `is.bimets`.

Value

This function returns an array built with requested information about the input time series list. In the case of `MODE=START2` or `MODE=END2` the output will be of class `matrix()`.
TSJOIN

Join Time Series

Description

This function returns the join of the two input time series. If the first time series overlaps the second time series, output data is taken from the first time series up to the starting date of the second time series, the remainder of the data being taken from the second time series.
A different joining period can be specified by using the JPRD argument.
The two time series must have the same frequency.

Examples

# create ts
ts1 = TIMESERIES(INTS(1,10), START=c(2004,2), FREQ=2,
UNITS='myUnits', TITLE='myTitle', SOURCE='mySource')
ts2 = TIMESERIES(INTS(1,20), START=c(2006,3), FREQ=4, SCALEFAC=1)
ts3 = TIMESERIES(INTS(1,30), START=c(2008,7), FREQ=12)

print(TSINFO(ts1, ts2, ts3, MODE='STARTY'))  # print ... c(2004,2006,2008)
print(TSINFO(ts1, ts2, ts3, MODE='ENDP'))  # print ... c(1,2,12)
print(TSINFO(ts1, ts2, ts3, MODE='FREQ'))  # print ... c(2,4,12)

# print ...
# [,1] [,2]
# [1,] 2004 2
# [2,] 2006 3
# [3,] 2008 7

print(TSINFO(ts1, ts2, ts3, MODE='END'))  # print ... c(2009.5, 2011.5, 2011.0)
print(TSINFO(ts1, ts2, ts3, MODE='FACTOR'))  # print ... c(0,1,0)
print(TSINFO(ts1, ts2, ts3, MODE='UNITS'))  # print ... c('myUnits','','')
Usage

`TSJOIN(x = NULL, y = NULL, JPRD = NULL, ALLOWGAP = FALSE, WARN = FALSE, avoidCompliance = FALSE, ...)`

Arguments

- **x**: First input time series that must satisfy the compliance control check defined in `is.bimets`.
- **y**: Second input time series that must satisfy the compliance control check defined in `is.bimets`.
- **JPRD**: This argument is for defining a joining period other than the starting period of the second time series, that is the default joining period. It must be defined as `JPRD = c(YEAR, PERIOD)` and must lie in the time range of the second time series. Users can convert a `Date()`, or a `yearmon()` or a `yearqtr()` to a `c(YEAR, PERIOD)` by using `date2yp`, `ym2yp`, `yq2yp`.
- **ALLOWGAP**: if `TRUE`, the possible gap between the two time series is filled with missing values `NA`, otherwise if the two time ranges do not overlap an error will be thrown.
- **WARN**: Print a warning message if the two time series do not overlap or if the first time series starts after the `JPRD`. The warning is shown only if `ALLOWGAP=TRUE`.
- **avoidCompliance**: If `TRUE`, compliance control check of input time series will be skipped. See `is.bimets`

Value

This function returns a BIMETS time series that is built by joining the two input time series.

t2=xts(dataF[,2],order.by=dataF[,1])
TABIT(t1,t2,TSJOIN(t1,t2,ALLOWGAP=TRUE,JPRD=yq2yp(as.yearqtr("2001 Q3"))))

#restore default
setBIMETScfg("BIMETS_CONF_CCT", 'TS')

---

**TSLAG**  

*Description*

This function lags the input time series by the specified number of time periods.

**Usage**

TSLAG(x = NULL, L = 1, avoidCompliance = FALSE, ...)

**Arguments**

- **x**: Input time series that must satisfy the compliance control check defined in `is.bimets`.
- **L**: Lag. Must be an integer, positive or negative.
- **avoidCompliance**: If TRUE, compliance control check of input time series will be skipped. See `is.bimets`
- **...**: Backward compatibility.

**Value**

This function returns a BIMETS time series built by lagging the input time series.

```

---

**TSLEAD**  
*Lead Time Series*

**Description**

This function leads the input time series by the specified number of time periods.

**Usage**

```r
TSLEAD(x = NULL, L = 1, avoidCompliance = FALSE, ...)
```

**Arguments**

- **x**: Input time series that must satisfy the compliance control check defined in `is.bimets`.
- **L**: Lead. Must be an integer, positive or negative.
- **avoidCompliance**: If TRUE, compliance control check of input time series will be skipped. See `is.bimets`
- **...**: Backward compatibility.

**Value**

This function returns a BIMETS time series built by leading the input time series.

ts1[5]=NA

#print TSLEAD
TABIT(ts1,TSLEAD(ts1,5))
```

---

**TSLOOK**

*Lookup a Time Series*

Description

This function returns the time range and the frequency of an input time series.

Usage

```r
TSLOOK(x=NULL, avoidCompliance=FALSE, ...)
```

Arguments

- **x**: Input time series that must satisfy the compliance control check defined in *is.bimets*.
- **avoidCompliance**: If TRUE, compliance control check of input time series will be skipped. See *is.bimets*.
- **...**: Backward compatibility.

Value

This function returns a list of numeric arrays built with the following elements:
- **STARTY**: will contain the value of the starting year
- **STARTP**: will contain the value of the starting period
- **ENDY**: will contain the value of the ending year
- **ENDP**: will contain the value of the ending period
- **FREQ**: will contain the value of the time series frequency

See Also

- NOELS

- BIMETS indexing
- fromBIMETStoXTS
- fromBIMETStoTS
TSMERGE

**Examples**

```r
# create series
ts1 = TSERIES(1:10, START = c(2000, 1), FREQ = 12)
t1Look = TSLOOK(t1)

print(t1Look$STARTY) # print...2000
print(t1Look$STARTP) # print...1
print(t1Look$ENDY) # print...2000
print(t1Look$ENDP) # print...10
print(t1Look$FREQ) # print...12
```

**Description**

This function merges and concatenates two or more time series of the same frequency. The output time series will be defined over the union of dates for which the input time series are defined, from the earliest starting date to the latest ending date.

For each period the output value will be set equal to the first non-missing value found in the list of the input time series, by using the order of the arguments. If all the input time series are missing at a period, then the output time series will be set to the missing value `NA` in the same period. Note that if the date spans of the input time series do not intersect, `TSMERGE(X1, X2, ..., XN)` returns a simple concatenation of `X1, X2, ..., XN`.

By defining the argument `fun`, the value of the output time series in a period can also be computed as a function of the values of the input time series in the same period.

**Usage**

`TSMERGE(..., fun = NULL, MV = FALSE, avoidCompliance = FALSE)`

**Arguments**

- `...` Input list of time series that must satisfy the compliance control check defined in `is.bimets`.
fun

By defining the argument fun, the value of the output time series in a period can also be computed as a function of the values of the input time series in the same period.

fun can assume the following string values:
- **AVE**: the value of the output time series in a period will be set equal to the average of all input time series values in the same period.
- **SUM**: the value of the output time series in a period will be set equal to the sum of all input time series values in the same period.
- **MAX**: the value of the output time series in a period will be set equal to the maximum of all input time series values in the same period.
- **MIN**: the value of the output time series in a period will be set equal to the minimum of all input time series values in the same period.

MV

If FALSE, the function defined in the argument fun will skip any missing values found in the input time series.

avoidCompliance

If TRUE, compliance control check of input time series will be skipped. See `is.bimets`

Value

This function returns a BIMETS time series built by merging two or more input time series.

Examples

```r
#DEFINE TS
n=10
ts1=TSERIES(n:1,START=c(1995,1),FREQ=1)
ts2=TSERIES(n:1,START=c(2000,1),FREQ=1)

# print TSMERGE
TABIT(ts1,ts2,TSMERGE(ts1,ts2,fun='SUM',MV=TRUE))

#TS D
n=20
ts1=TSERIES(n:1,START=c(1999,360),FREQ='D')
```
TSPROJECT

### Project a Time series

**Description**

This function projects the input time series into a time interval. The output class can be either a time series (default) or a one-dimensional array if the argument `ARRAY=TRUE`.

**Usage**

```
TSPROJECT(x=NULL, TSRANGE=NULL, ARRAY=FALSE,
           EXTEND=FALSE, avoidCompliance=FALSE,...)
```

**Arguments**

- **x**
  
  Input time series that must satisfy the compliance control check defined in `is.bimets`.

- **TSRANGE**
  
  Date range of data projection. `TSRANGE` must be specified as a numerical array composed by starting year, starting period, ending year and ending period of projection, i.e. `TSRANGE=c(START_YEAR,START_PERIOD,END_YEAR,END_PERIOD)`.

- **ARRAY**
  
  If `TRUE` this function will return a numerical array built with observation values that lie in the specified time range. If `FALSE` (default) the output will be a time series.

- **EXTEND**
  
  If `TRUE` and in the case that the input time series does not overlap with the provided `TSRANGE`, the output time series will be extended over the `TSRANGE` by inserting missing values `NA` into the new observations.

- **avoidCompliance**
  
  If `TRUE`, compliance control check of input time series will be skipped. See `is.bimets`.

- **...**
  
  Backward compatibility.

**Value**

This function returns a BIMETS time series, or a numerical array if the argument `ARRAY=TRUE`, built by projecting the input time series into the provided `TSRANGE`.

```r
ts2 = TSERIES(n=1, START=c(2000,1), FREQ='D')
ts2[5]=NA
ts1[10]=NA

# print TSMERGE
TABIT(ts1, ts2, TSMERGE(ts1, ts2, fun='SUM', MV=TRUE))

print(TSPROJECT(ts1,TSRANGE=c(2002,1,2005,1))) # print projected ts from 2002 to 2005

print(TSPROJECT(ts1,TSRANGE=c(2001,1,2004,1),ARRAY=TRUE)) # print c(2,3,4,5)

print(TSPROJECT(ts1,TSRANGE=c(1998,1,2002,1),EXTEND=TRUE,ARRAY=TRUE))
# print c(NA,NA,1,2,3)

TSTRIM

Trim a Time Series

Description

This function removes trailing or leading missing values NA from the input array or the input time series. Users can provide the value to be removed other than NA missing value by using the argument VALUE.

Usage

TSTRIM(x=NULL, VALUE=NA, TRAIL=TRUE, LEAD=TRUE, avoidCompliance=FALSE, ...)

Arguments

x Input numerical array or time series that must satisfy the compliance control check defined in is.bimets.
VALUE Target value to be removed. Default to missing value NA.
TRAIL If TRUE this function will remove trailing target values from the input time series.
LEAD If TRUE this function will remove leading target values from the input time series.
avoidCompliance If TRUE, compliance control check of input time series will be skipped. See is.bimets
... Backward compatibility.
ym2yp

Value
This function returns an object of the same class of the input, i.e. an array or a BIMETS time series, built by removing leading and trailing user-defined values.

```r
#TS A
n=10
tsl=TSERIES(c(NA,1:n,NA),START=c(2000,1),FREQ='A')
TABIT(tsl,TSTRIM(tsl))

tsl=TSERIES(c(NA,1:n,NA),START=c(2000,1),FREQ='A')
TABIT(tsl,TSTRIM(tsl,TRAIL=FALSE))

tsl=TSERIES(c(NA,1:n,NA),START=c(2000,1),FREQ='A')
TABIT(tsl,TSTRIM(tsl,LEAD=FALSE))

tsl=TSERIES(c(0,0,NA,1:n,NA,0),START=c(2000,1),FREQ='A')
TABIT(tsl,TSTRIM(tsl,0))
```

ym2yp

yearmon to Year-Period Conversion

Description
This function transforms an input variable of class yearmon() into an equivalent two-dimensional numerical array of type c(YEAR, PERIOD).

Usage
ym2yp(x = NULL)

Arguments

x Input of class yearmon()
Value

This function returns a two-dimensional numerical array of type c(YEAR,PERIOD).

See Also

date2yp
yq2yp
GETDATE

Examples

#day and month names can change depending on locale
Sys.setlocale('LC_ALL','C')
Sys.setlocale('LC_TIME','C')

print(ym2yp(as.yearmon("Dec 2013"))); # print c(2013,12)
print(ym2yp(c(as.yearmon('Jan 2000'),as.yearmon('Dec 1987'),
                   as.yearmon('Jan 2003'),as.yearmon('Mar 2012'))))

yq2yp yearqtr to Year-Period Conversion

Description

This function transforms an input variable of class yearqtr() into an equivalent two-dimensional numerical array of type c(YEAR,PERIOD).

Usage

yq2yp(x = NULL)

Arguments

x Input of class yearmon()

Value

This function returns a two-dimensional numerical array of type c(YEAR,PERIOD).
