Prope

 $\chi^2$  and t distributions

## Joint moment-generating function Of a p-dimensional random vector $\mathbf{x}$

• 
$$M_{\mathbf{x}}(\mathbf{t}) = E\left(e^{\mathbf{t}'\mathbf{x}}\right)$$
  
• For example,  $M_{(x_1,x_2,x_3)}(t_1,t_2,t_3) = E\left(e^{x_1t_1+x_2t_2+x_3t_3}\right)$ 

Section 4.3 of *Linear models in statistics* has some material on moment-generating functions (optional).

- Joint moment-generating functions correspond uniquely to joint probability distributions.
- Two random vectors x<sub>1</sub> and x<sub>2</sub> are independent if and only if the moment-generating function of their joint distribution is the product of their moment-generating functions.

These results assume only that the moment-generating functions exist in a neighborhood of  $\mathbf{t} = \mathbf{0}$ . Nothing else is required.

#### A helpful distinction

• If  $x_1$  and  $x_2$  are independent,

$$M_{x_1+x_2}(t) = M_{x_1}(t)M_{x_2}(t)$$

•  $x_1$  and  $x_2$  are independent if and only if

$$M_{x_1,x_2}(t_1,t_2) = M_{x_1}(t_1)M_{x_2}(t_2)$$

# Theorem: Functions of independent random vectors are independent

Show  $\mathbf{x}_1$  and  $\mathbf{x}_2$  independent implies that  $\mathbf{y}_1 = g_1(\mathbf{x}_1)$  and  $\mathbf{y}_2 = g_2(\mathbf{x}_2)$  are independent.

Let

$$\mathbf{y} = \left(\frac{\mathbf{y}_1}{\mathbf{y}_2}\right) = \left(\frac{g_1(\mathbf{x}_1)}{g_2(\mathbf{x}_2)}\right) \text{ and } \mathbf{t} = \left(\frac{\mathbf{t}_1}{\mathbf{t}_2}\right). \text{ Then}$$

$$M_{\mathbf{y}}(\mathbf{t}) = E\left(e^{\mathbf{t}'\mathbf{y}}\right)$$

$$= E\left(e^{\mathbf{t}'_1\mathbf{y}_1 + \mathbf{t}'_2\mathbf{y}_2}\right) = E\left(e^{\mathbf{t}'_1\mathbf{y}_1}e^{\mathbf{t}'_2\mathbf{y}_2}\right)$$

$$= E\left(e^{\mathbf{t}'_1g_1(\mathbf{x}_1)}e^{\mathbf{t}'_2g_2(\mathbf{x}_2)}\right)$$

$$= \int \int e^{\mathbf{t}'_1g_1(\mathbf{x}_1)}e^{\mathbf{t}'_2g_2(\mathbf{x}_2)}f_{\mathbf{x}_1}(\mathbf{x}_1)f_{\mathbf{x}_2}(\mathbf{x}_2) d(\mathbf{x}_1)d(\mathbf{x}_2)$$

$$= M_{g_1(\mathbf{x}_1)}(\mathbf{t}_1)M_{g_2(\mathbf{x}_2)}(\mathbf{t}_2)$$

$$= M_{\mathbf{y}_1}(\mathbf{t}_1)M_{\mathbf{y}_2}(\mathbf{t}_2)$$

So  $\mathbf{y}_1$  and  $\mathbf{y}_2$  are independent.

 $\chi^2$  and t distributions

 $M_{A\mathbf{x}}(\mathbf{t}) = M_{\mathbf{x}}(A'\mathbf{t})$ Analogue of  $M_{ax}(t) = M_x(at)$ 

$$M_{A\mathbf{x}}(\mathbf{t}) = E\left(e^{\mathbf{t}'A\mathbf{x}}\right)$$
$$= E\left(e^{\left(A'\mathbf{t}\right)'\mathbf{x}}\right)$$
$$= M_{\mathbf{x}}(A'\mathbf{t})$$

Note that **t** is the same length as  $\mathbf{y} = A\mathbf{x}$ : The number of rows in A.

Moment-generating Functions

Definition

Prop

 $\chi^2$  and t distribution

 $M_{\mathbf{x}+\mathbf{c}}(\mathbf{t}) = e^{\mathbf{t'c}} M_{\mathbf{x}}(\mathbf{t})$ Analogue of  $M_{x+c}(t) = e^{ct} M_x(t)$ 

$$M_{\mathbf{x}+\mathbf{c}}(\mathbf{t}) = E\left(e^{\mathbf{t}'(\mathbf{x}+\mathbf{c})}\right)$$
$$= E\left(e^{\mathbf{t}'\mathbf{x}+\mathbf{t}'\mathbf{c}}\right)$$
$$= e^{\mathbf{t}'\mathbf{c}} E\left(e^{\mathbf{t}'\mathbf{x}}\right)$$
$$= e^{\mathbf{t}'\mathbf{c}} M_{\mathbf{x}}(\mathbf{t})$$

### Distributions may be defined in terms of moment-generating functions

Build up the multivariate normal from univariate normals.

- If  $y \sim N(\mu, \sigma^2)$ , then  $M_y(t) = e^{\mu t + \frac{1}{2}\sigma^2 t^2}$
- Moment-generating functions correspond uniquely to probability distributions.
- So define a normal random variable with expected value  $\mu$  and variance  $\sigma^2$  as a random variable with moment-generating function  $e^{\mu t + \frac{1}{2}\sigma^2 t^2}$ .
- This has one surprising consequence ...

#### Degenerate random variables

A degenerate random variable has all the probability

concentrated at a single value, say  $Pr\{y = y_0\} = 1$ . Then

$$\begin{split} M_{y}(t) &= E(e^{yt}) \\ &= \sum_{y} e^{yt} p(y) \\ &= e^{y_{0}t} \cdot p(y_{0}) \\ &= e^{y_{0}t} \cdot 1 \\ &= e^{y_{0}t} \end{split}$$

## If $Pr\{y = y_0\} = 1$ , then $M_y(t) = e^{y_0 t}$

- This is of the form  $e^{\mu t + \frac{1}{2}\sigma^2 t^2}$  with  $\mu = y_0$  and  $\sigma^2 = 0$ .
- So  $y \sim N(y_0, 0)$ .
- That is, degenerate random variables are "normal" with variance zero.
- Call them *singular* normals.
- This will be surprisingly handy later.

 $\chi^2$  and t distributions

#### Independent standard normals

Let 
$$z_1, \ldots, z_p \stackrel{i.i.d.}{\sim} N(0,1).$$

$$\mathbf{z} = \left(egin{array}{c} z_1 \ dots \ z_p \end{array}
ight)$$

$$E(\mathbf{z}) = \mathbf{0} \qquad \quad cov(\mathbf{z}) = I_p$$

#### Moment-generating function of $\mathbf{z}$ Using $e^{\mu t + \frac{1}{2}\sigma^2 t^2}$

$$M_{\mathbf{z}}(\mathbf{t}) = \prod_{j=1}^{p} M_{z_j}(t_j)$$
$$= \prod_{j=1}^{p} e^{\frac{1}{2}t_j^2}$$
$$= e^{\frac{1}{2}\sum_{j=1}^{p} t_j^2}$$
$$= e^{\frac{1}{2}\mathbf{t't}}$$

Transform  $\mathbf{z}$  to get a general multivariate normal Remember: A non-negative definite means  $\mathbf{v}' A \mathbf{v} \ge 0$ 

- Let  $\Sigma$  be a  $p \times p$  symmetric non-negative definite matrix and  $\mu \in \mathbb{R}^p$ . Let  $\mathbf{y} = \Sigma^{1/2} \mathbf{z} + \mu$ .
  - The elements of **y** are linear combinations of independent standard normals.
  - Linear combinations of normals should be normal.
  - **y** has a multivariate distribution.
  - We'd like to call **y** a *multivariate normal*.

15/36

Moment-generating function of  $\mathbf{y} = \Sigma^{1/2} \mathbf{z} + \boldsymbol{\mu}$ Remember:  $M_{A\mathbf{x}}(\mathbf{t}) = M_{\mathbf{x}}(A'\mathbf{t})$  and  $M_{\mathbf{x}+\mathbf{c}}(\mathbf{t}) = e^{\mathbf{t}'\mathbf{c}}M_{\mathbf{x}}(\mathbf{t})$  and  $M_{\mathbf{z}}(\mathbf{t}) = e^{\frac{1}{2}\mathbf{t}'\mathbf{t}}$ 

$$\begin{split} M_{\mathbf{y}}(\mathbf{t}) &= M_{\Sigma^{1/2}\mathbf{z}+\mu}(\mathbf{t}) \\ &= e^{\mathbf{t}'\mu} M_{\Sigma^{1/2}\mathbf{z}}(\mathbf{t}) \\ &= e^{\mathbf{t}'\mu} M_{\mathbf{z}}(\Sigma^{1/2}\mathbf{t}) \\ &= e^{\mathbf{t}'\mu} M_{\mathbf{z}}(\Sigma^{1/2}\mathbf{t}) \\ &= e^{\mathbf{t}'\mu} e^{\frac{1}{2}(\Sigma^{1/2}\mathbf{t})'(\Sigma^{1/2}\mathbf{t})} \\ &= e^{\mathbf{t}'\mu} e^{\frac{1}{2}\mathbf{t}'\Sigma^{1/2}\Sigma^{1/2}\mathbf{t}} \\ &= e^{\mathbf{t}'\mu} e^{\frac{1}{2}\mathbf{t}'\Sigma\mathbf{t}} \\ &= e^{\mathbf{t}'\mu+\frac{1}{2}\mathbf{t}'\Sigma\mathbf{t}} \end{split}$$

So define a multivariate normal random variable **y** as one with moment-generating function  $M_{\mathbf{y}}(\mathbf{t}) = e^{\mathbf{t'}\boldsymbol{\mu}} e^{\frac{1}{2}\mathbf{t'}\Sigma\mathbf{t}}$ .

 $\chi^2$  and t distributions

Compare univariate and multivariate normal moment-generating functions

Univariate 
$$M_y(t) = e^{\mu t + \frac{1}{2}\sigma^2 t^2}$$

Multivariate 
$$M_{\mathbf{x}}(\mathbf{t}) = e^{\mathbf{t}'\boldsymbol{\mu}} e^{\frac{1}{2}\mathbf{t}'\Sigma\mathbf{t}}$$

So the univariate normal is a special case of the multivariate normal with p = 1.

 $\chi^2$  and t distributions

Mean and covariance matrix For a univariate normal,  $E(y) = \mu$  and  $Var(y) = \sigma^2$ 

Recall 
$$\mathbf{y} = \Sigma^{1/2} \mathbf{z} + \boldsymbol{\mu}$$
.

$$E(\mathbf{y}) = \boldsymbol{\mu}$$
  

$$cov(\mathbf{y}) = \Sigma^{1/2} cov(\mathbf{z}) \Sigma^{1/2} \boldsymbol{\mu}$$
  

$$= \Sigma^{1/2} I \Sigma^{1/2} \boldsymbol{\mu}$$
  

$$= \Sigma$$

We will say  $\mathbf{y}$  is multivariate normal with expected value  $\boldsymbol{\mu}$  and variance-covariance matrix  $\Sigma$ , and write  $\mathbf{y} \sim N_p(\boldsymbol{\mu}, \Sigma)$ .

Note that because  $M_{\mathbf{y}}(\mathbf{t}) = e^{\mathbf{t}'\boldsymbol{\mu}} e^{\frac{1}{2}\mathbf{t}'\Sigma\mathbf{t}}$ ,  $\boldsymbol{\mu}$  and  $\Sigma$  completely determine the distribution.

#### Probability density function of $\mathbf{y} \sim N_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ Remember, $\boldsymbol{\Sigma}$ is only positive *semi*-definite.

It is easy to write down the density of  $\mathbf{z} \sim N_p(\mathbf{0}, I)$  as a product of standard normals.

If  $\Sigma$  is strictly positive definite (and not otherwise), the density of  $\mathbf{y} = \Sigma^{1/2} \mathbf{z} + \boldsymbol{\mu}$  can be obtained using the Jacobian Theorem as

$$f(\mathbf{y}) = \frac{1}{|\Sigma|^{\frac{1}{2}} (2\pi)^{\frac{p}{2}}} \exp\left\{-\frac{1}{2}(\mathbf{y} - \boldsymbol{\mu})' \Sigma^{-1}(\mathbf{y} - \boldsymbol{\mu})\right\}$$

This is usually how the multivariate normal is defined.

#### $\Sigma$ positive definite?

- Positive definite means that for any non-zero p × 1 vector a, we have a'Σa > 0.
- Since the one-dimensional random variable  $w = \sum_{i=1}^{p} a_i y_i$ may be written as  $W = \mathbf{a}' \mathbf{y}$  and  $Var(w) = cov(\mathbf{a}' \mathbf{y}) = \mathbf{a}' \Sigma \mathbf{a}$ , it is natural to require that  $\Sigma$ be positive definite.
- All it means is that every non-zero linear combination of **y** values has a positive variance. Often, this is what you want.

#### Singular normal: $\Sigma$ is positive *semi*-definite.

Suppose there is  $\mathbf{a} \neq \mathbf{0}$  with  $\mathbf{a}' \Sigma \mathbf{a} = 0$ . Let  $w = \mathbf{a}' \mathbf{y}$ .

- Then  $Var(w) = Var(\mathbf{a}'\mathbf{y}) = \mathbf{a}'\Sigma\mathbf{a} = 0$ . That is, w has a degenerate distribution (but it's still still normal).
- In this case we describe the distribution of **y** as a *singular* multivariate normal.
- Including the singular case saves a lot of extra work in later proofs.
- We will insist that a singular multivariate normal is still multivariate normal, even though it has no density.

 $\chi^2$  and t distributions

Distribution of  $A\mathbf{y}$ Recall  $\mathbf{y} \sim N_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$  means  $M_{\mathbf{y}}(\mathbf{t}) = e^{\mathbf{t}'\boldsymbol{\mu} + \frac{1}{2}\mathbf{t}'\boldsymbol{\Sigma}\mathbf{t}}$ 

Let  $\mathbf{y} \sim N_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ , and  $\mathbf{w} = A\mathbf{y}$ , where A is an  $r \times p$  matrix.

$$\begin{split} M_{\mathbf{w}}(\mathbf{t}) &= M_{A\mathbf{y}}(\mathbf{t}) \\ &= M_{\mathbf{y}}(A'\mathbf{t}) \\ &= e^{(A'\mathbf{t})'\boldsymbol{\mu}} e^{\frac{1}{2}(A'\mathbf{t})'\boldsymbol{\Sigma}(A'\mathbf{t})} \\ &= e^{\mathbf{t}'(A\boldsymbol{\mu})} e^{\frac{1}{2}\mathbf{t}'(A\boldsymbol{\Sigma}A')\mathbf{t}} \\ &= e^{\mathbf{t}'(A\boldsymbol{\mu}) + \frac{1}{2}\mathbf{t}'(A\boldsymbol{\Sigma}A')\mathbf{t}} \end{split}$$

Recognize moment-generating function and conclude

$$\mathbf{w} \sim N_r(A\boldsymbol{\mu}, A\Sigma A')$$

 $\chi^2$  and t distributions

#### Exercise Use moment-generating functions, of course.

Let 
$$\mathbf{y} \sim N_p(\boldsymbol{\mu}, \boldsymbol{\Sigma}).$$

## Show $\mathbf{y} + \mathbf{c} \sim N_p(\boldsymbol{\mu} + \mathbf{c}, \boldsymbol{\Sigma}).$

Zero covariance implies independence for the multivariate normal.

- Independence always implies zero covariance.
- For the multivariate normal, zero covariance also implies independence.
- The multivariate normal is the only continuous distribution with this property.

 $\chi^2$  and t distributions

Show zero covariance implies independence By showing  $M_{\mathbf{y}}(\mathbf{t}) = M_{\mathbf{y}_1}(\mathbf{t}_1)M_{\mathbf{y}_2}(\mathbf{t}_2)$ 

Let  $\mathbf{y} \sim N(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ , with

$$\mathbf{y} = \left( egin{array}{c|c} \mathbf{y}_1 \ \mathbf{y}_2 \end{array} 
ight) \quad \boldsymbol{\mu} = \left( egin{array}{c|c} \boldsymbol{\mu}_1 \ \boldsymbol{\mu}_2 \end{array} 
ight) \quad \boldsymbol{\Sigma} = \left( egin{array}{c|c} \Sigma_1 & \mathbf{0} \ \hline \mathbf{0} & \Sigma_2 \end{array} 
ight) \quad \mathbf{t} = \left( egin{array}{c|c} \mathbf{t}_1 \ \hline \mathbf{t}_2 \end{array} 
ight)$$

$$M_{\mathbf{y}}(\mathbf{t}) = E\left(e^{\mathbf{t}'\mathbf{y}}\right)$$
$$= E\left(e^{\left(\frac{\mathbf{t}_{1}}{\mathbf{t}_{2}}\right)'\mathbf{y}}\right)$$
$$= \dots$$

Continuing the calculation: 
$$M_{\mathbf{y}}(\mathbf{t}) = e^{\mathbf{t}'\boldsymbol{\mu} + \frac{1}{2}\mathbf{t}'\Sigma\mathbf{t}}$$
  
 $\mathbf{y} = \begin{pmatrix} \mathbf{y}_1 \\ \mathbf{y}_2 \end{pmatrix} \quad \boldsymbol{\mu} = \begin{pmatrix} \underline{\mu}_1 \\ \underline{\mu}_2 \end{pmatrix} \quad \boldsymbol{\Sigma} = \begin{pmatrix} \underline{\Sigma}_1 & \mathbf{0} \\ \mathbf{0} & \underline{\Sigma}_2 \end{pmatrix} \quad \mathbf{t} = \begin{pmatrix} \mathbf{t}_1 \\ \mathbf{t}_2 \end{pmatrix}$ 

$$M_{\mathbf{y}}(\mathbf{t}) = E\left(e^{\left(\frac{\mathbf{t}_{1}}{\mathbf{t}_{2}}\right)'\mathbf{y}}\right)$$

$$= \exp\left\{\left(\mathbf{t}_{1}'|\mathbf{t}_{2}'\right)\left(\frac{\mu_{1}}{\mu_{2}}\right)\right\}\exp\left\{\frac{1}{2}(\mathbf{t}_{1}'|\mathbf{t}_{2}')\left(\frac{\Sigma_{1}}{\mathbf{0}}\mid\mathbf{0}\right)\left(\frac{\mathbf{t}_{1}}{\mathbf{t}_{2}}\right)\right\}$$

$$= e^{\mathbf{t}_{1}'\mu_{1}+\mathbf{t}_{2}'\mu_{2}}\exp\left\{\frac{1}{2}\left(\mathbf{t}_{1}'\Sigma_{1}|\mathbf{t}_{2}'\Sigma_{2}\right)\left(\frac{\mathbf{t}_{1}}{\mathbf{t}_{2}}\right)\right\}$$

$$= e^{\mathbf{t}_{1}'\mu_{1}+\mathbf{t}_{2}'\mu_{2}}\exp\left\{\frac{1}{2}\left(\mathbf{t}_{1}'\Sigma_{1}\mathbf{t}_{1}+\mathbf{t}_{2}'\Sigma_{2}\mathbf{t}_{2}\right)\right\}$$

$$= e^{\mathbf{t}_{1}'\mu_{1}}e^{\mathbf{t}_{2}'\mu_{2}}e^{\frac{1}{2}(\mathbf{t}_{1}'\Sigma_{1}\mathbf{t}_{1})}e^{\frac{1}{2}(\mathbf{t}_{2}'\Sigma_{2}\mathbf{t}_{2})}$$

$$= e^{\mathbf{t}_{1}'\mu_{1}+\frac{1}{2}(\mathbf{t}_{1}'\Sigma_{1}\mathbf{t}_{1})}e^{\mathbf{t}_{2}'\mu_{2}+\frac{1}{2}(\mathbf{t}_{2}'\Sigma_{2}\mathbf{t}_{2})}$$

$$= M_{\mathbf{y}_{1}}(\mathbf{t}_{1})M_{\mathbf{y}_{2}}(\mathbf{t}_{2})$$

So  $\mathbf{y}_1$  and  $\mathbf{y}_2$  are independent.

Let  $y_1 \sim N(1,2)$ ,  $y_2 \sim N(2,4)$  and  $y_3 \sim N(6,3)$  be independent, with  $w_1 = y_1 + y_2$  and  $w_2 = y_2 + y_3$ . Find the joint distribution of  $w_1$  and  $w_2$ .

$$\left(\begin{array}{c} w_1\\ w_2 \end{array}\right) = \left(\begin{array}{cc} 1 & 1 & 0\\ 0 & 1 & 1 \end{array}\right) \left(\begin{array}{c} y_1\\ y_2\\ y_3 \end{array}\right)$$

$$\mathbf{w} = A\mathbf{y} \sim N(A\boldsymbol{\mu}, A\boldsymbol{\Sigma}A')$$

 $\chi^2$  and t distributions

 $\mathbf{w} = A\mathbf{y} \sim N(A\boldsymbol{\mu}, A\boldsymbol{\Sigma}A')$  $y_1 \sim N(1, 2), y_2 \sim N(2, 4) \text{ and } y_3 \sim N(6, 3) \text{ are independent}$ 

$$A\mu = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix} \begin{pmatrix} 1 \\ 2 \\ 6 \end{pmatrix} = \begin{pmatrix} 3 \\ 8 \end{pmatrix}$$
$$A\Sigma A' = \begin{pmatrix} 1 & 1 & 0 \\ 0 & 1 & 1 \end{pmatrix} \begin{pmatrix} 2 & 0 & 0 \\ 0 & 4 & 0 \\ 0 & 0 & 3 \end{pmatrix} \begin{pmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{pmatrix}$$
$$= \begin{pmatrix} 6 & 4 \\ 4 & 7 \end{pmatrix}$$

 $\chi^2$  and t distributions

Marginal distributions are multivariate normal  $\mathbf{y} \sim N_p(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ , so  $\mathbf{w} = A\mathbf{y} \sim N(A\boldsymbol{\mu}, A\boldsymbol{\Sigma}A')$ 

Find the distribution of

$$\begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} y_1 \\ y_2 \\ y_3 \\ y_4 \end{pmatrix} = \begin{pmatrix} y_2 \\ y_4 \end{pmatrix}$$

Bivariate normal. The expected value is easy.

 $\chi^2$  and t distributions

#### Covariance matrix

$$\begin{aligned} \cos(A\mathbf{y}) &= A\Sigma A' \\ &= \begin{pmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 \end{pmatrix} \begin{pmatrix} \sigma_1^2 & \sigma_{1,2} & \sigma_{1,3} & \sigma_{1,4} \\ \sigma_{1,2} & \sigma_2^2 & \sigma_{2,3} & \sigma_{2,4} \\ \sigma_{1,3} & \sigma_{2,3} & \sigma_3^2 & \sigma_{3,4} \\ \sigma_{1,4} & \sigma_{2,4} & \sigma_{3,4} & \sigma_4^2 \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} \sigma_{1,2} & \sigma_2^2 & \sigma_{2,3} & \sigma_{2,4} \\ \sigma_{1,4} & \sigma_{2,4} & \sigma_{3,4} & \sigma_4^2 \end{pmatrix} \begin{pmatrix} 0 & 0 \\ 1 & 0 \\ 0 & 0 \\ 0 & 1 \end{pmatrix} \\ &= \begin{pmatrix} \sigma_2^2 & \sigma_{2,4} \\ \sigma_{2,4} & \sigma_4^2 \end{pmatrix} \end{aligned}$$

Marginal distributions of a multivariate normal are multivariate normal, with the original means, variances and covariances.

#### Summary

- If **c** is a vector of constants,  $\mathbf{x} + \mathbf{c} \sim N(\mathbf{c} + \boldsymbol{\mu}, \boldsymbol{\Sigma})$
- If A is a matrix of constants,  $A \mathbf{x} \sim N(A \boldsymbol{\mu}, A \boldsymbol{\Sigma} A')$
- Linear combinations of multivariate normals are multivariate normal.
- All the marginals (dimension less than p) of **x** are (multivariate) normal, but it is possible in theory to have a collection of univariate normals whose joint distribution is not multivariate normal.
- For the multivariate normal, zero covariance implies independence. The multivariate normal is the only continuous distribution with this property.

 $\chi^2$  and t distributions

Showing 
$$(\mathbf{x} - \boldsymbol{\mu})' \Sigma^{-1} (\mathbf{x} - \boldsymbol{\mu}) \sim \chi^2(p)$$
  
  $\Sigma$  has to be positive definite this time

$$\mathbf{x} \sim N(\boldsymbol{\mu}, \boldsymbol{\Sigma})$$
$$\mathbf{y} = \mathbf{x} - \boldsymbol{\mu} \sim N(\mathbf{0}, \boldsymbol{\Sigma})$$
$$\mathbf{z} = \boldsymbol{\Sigma}^{-\frac{1}{2}} \mathbf{y} \sim N\left(\mathbf{0}, \boldsymbol{\Sigma}^{-\frac{1}{2}} \boldsymbol{\Sigma} \boldsymbol{\Sigma}^{-\frac{1}{2}}\right)$$
$$= N\left(\mathbf{0}, \boldsymbol{\Sigma}^{-\frac{1}{2}} \boldsymbol{\Sigma}^{\frac{1}{2}} \boldsymbol{\Sigma}^{\frac{1}{2}} \boldsymbol{\Sigma}^{-\frac{1}{2}}\right)$$
$$= N(\mathbf{0}, I)$$

So  $\mathbf{z}$  is a vector of p independent standard normals, and

$$\mathbf{y}' \Sigma^{-1} \mathbf{y} = (\Sigma^{-\frac{1}{2}} \mathbf{y})' (\Sigma^{-\frac{1}{2}} \mathbf{y}) = \mathbf{z}' \mathbf{z} = \sum_{j=1}^{p} z_i^2 \sim \chi^2(p)$$

Properti

 $\chi^2$  and t distributions

 $\overline{x}$  and  $s^2$  independent  $x_1, \ldots, x_n \stackrel{i.i.d}{\sim} N(\mu, \sigma^2)$ 

$$\mathbf{x} = \begin{pmatrix} x_1 \\ \vdots \\ x_n \end{pmatrix} \sim N\left(\mu \mathbf{1}, \sigma^2 I\right) \qquad \mathbf{y} = \begin{pmatrix} x_1 - \overline{x} \\ \vdots \\ x_n - \overline{x} \\ \overline{x} \end{pmatrix} = A\mathbf{x}$$

Note A is  $(n+1) \times n$ , so  $cov(A\mathbf{x}) = \sigma^2 \mathbf{A}\mathbf{A}'$  is  $(n+1) \times (n+1)$ , singular.

 $\chi^2$  and t distributions

#### The argument

$$\mathbf{y} = A\mathbf{x} = \begin{pmatrix} x_1 - \overline{x} \\ \vdots \\ x_n - \overline{x} \\ \overline{x} \end{pmatrix} = \begin{pmatrix} \mathbf{y}_2 \\ \mathbf{y}_2 \\ \hline \mathbf{y}_2 \\ \hline \overline{x} \end{pmatrix}$$

- **y** is multivariate normal.
- $Cov(\overline{x}, (x_j \overline{x})) = 0$  (Exercise)
- So  $\overline{x}$  and  $\mathbf{y}_2$  are independent.
- So  $\overline{x}$  and  $S^2 = g(\mathbf{y}_2)$  are independent.

 $\chi^2$  and t distributions

#### Leads to the t distribution

#### If

- $z \sim N(0, 1)$  and
- $y \sim \chi^2(\nu)$  and
- z and y are independent, then

$$T = \frac{z}{\sqrt{y/\nu}} \sim t(\nu)$$

#### Random sample from a normal distribution

Let 
$$x_1, \ldots, x_n \stackrel{i.i.d.}{\sim} N(\mu, \sigma^2)$$
. Then  
•  $\frac{\sqrt{n}(\overline{x}-\mu)}{\sigma} \sim N(0, 1)$  and  
•  $\frac{(n-1)S^2}{\sigma^2} \sim \chi^2(n-1)$  and

• These quantities are independent, so

$$T = \frac{\sqrt{n}(\overline{x} - \mu)/\sigma}{\sqrt{\frac{(n-1)S^2}{\sigma^2}/(n-1)}}$$
$$= \frac{\sqrt{n}(\overline{x} - \mu)}{S} \sim t(n-1)$$
