## Factorial ANOVA

## More than one categorical explanatory variable

This slide show is a free open source document. See the last slide for copyright information.

## Factorial ANOVA

- Categorical explanatory variables are called factors
- More than one at a time
- Designed for true experiments, but also useful with observational data
- If there are observations at all combinations of explanatory variable values, it's called a complete factorial design (as opposed to a fractional factorial).

## The potato study

- Cases are potatoes
- Inoculate with bacteria, store for a fixed time period.
- Response variable is diameter of rotten spot in millimeters
- Two explanatory variables, randomly assigned
- Bacteria Type $(1,2,3)$
- Temperature (1=Cool, 2=Warm)

## Two-factor design

|  | Bacteria Type |  |  |
| :--- | :---: | :---: | :---: |
| Temp | 1 | 2 | 3 |
| 1=Cool |  |  |  |
| 2=Warm |  |  |  |

Six treatment conditions

## Factorial experiments

- Allow more than one factor to be investigated in the same study: Efficiency!
- Allow the scientist to see whether the effect of an explanatory variable depends on the value of another explanatory variable: Interactions
- Thank you again, Mr. Fisher.

Model: Data are normal with equal variance and conditional (cell) means $\mu_{i, j}$

|  | Bacteria Type |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Temp | 1 | 2 | 3 |  |
| 1=Cool | $\mu_{1,1}$ | $\mu_{1,2}$ | $\mu_{1,3}$ | $\frac{\mu_{1,1}+\mu_{1,2}+\mu_{1,3}}{3}$ |
| $2=$ Warm | $\mu_{2,1}$ | $\mu_{2,2}$ | $\mu_{2,3}$ | $\frac{\mu_{2,1}+\mu_{2,2}+\mu_{2,3}}{3}$ |
|  | $\frac{\mu_{1,1}+\mu_{2,1}}{2}$ | $\frac{\mu_{1,2}+\mu_{2,2}}{2}$ | $\frac{\mu_{1,3}+\mu_{2,3}}{2}$ | $\mu$ |

## Tests

- Main effects: Differences among marginal means
- Interactions: Differences between differences (What is the effect of Factor A? It depends on level of Factor B.)

## To understand the interaction, plot the means

## Either Way

## Non-parallel profiles = Interaction

## Main effects for both variables, no interaction

## Main effect for Bacteria only

## Main Effect for Temperature Only

## Both Main Effects, and the Interaction

## Should you interpret the main effects?

## Testing Contrasts

|  | Bacteria Type |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Temp | 1 | 2 | 3 |  |
| 1=Cool | $\mu_{1,1}$ | $\mu_{1,2}$ | $\mu_{1,3}$ | $\frac{\mu_{1,1}+\mu_{1,2}+\mu_{1,3}}{3}$ |
| 2=Warm | $\mu_{2,1}$ | $\mu_{2,2}$ | $\mu_{2,3}$ | $\frac{\mu_{2,1}+\mu_{2,2}+\mu_{2,3}}{3}$ |
|  | $\frac{\mu_{1,1}+\mu_{2,1}}{2}$ | $\frac{\mu_{1,2}+\mu_{2,2}}{2}$ | $\frac{\mu_{1,3}+\mu_{2,3}}{2}$ | $\mu$ |

- Differences between marginal means are definitely contrasts
- Interactions are also sets of contrasts

## Interactions are sets of Contrasts

|  | Bacteria Type |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Temp | 1 | 2 | 3 |  |
| 1=Cool | $\mu_{1,1}$ | $\mu_{1,2}$ | $\mu_{1,3}$ | $\frac{\mu_{1,1}+\mu_{1,2}+\mu_{1,3}}{3}$ |
| 2=Warm | $\mu_{2,1}$ | $\mu_{2,2}$ | $\mu_{2,3}$ | $\frac{\mu_{2,1}+\mu_{2,2}+\mu_{2,3}}{3}$ |
|  | $\frac{\mu_{1,1}+\mu_{2,1}}{2}$ | $\frac{\mu_{1,2}+\mu_{2,2}}{2}$ | $\frac{\mu_{1,3}+\mu_{2,3}}{2}$ | $\mu$ |

- $H_{0}: \mu_{1,1}-\mu_{2,1}=\mu_{1,2}-\mu_{2,2}=\mu_{1,3}-\mu_{2,3}$
- $H_{0}: \mu_{1,2}-\mu_{1,1}=\mu_{2,2}-\mu_{2,1}$ and

$$
\mu_{1,3}-\mu_{1,2}=\mu_{2,3}-\mu_{2,2}
$$

## Interactions are sets of Contrasts

- $H_{0}: \mu_{1,1}-\mu_{2,1}=\mu_{1,2}-\mu_{2,2}=\mu_{1,3}-\mu_{2,3}$
- $H_{0}: \mu_{1,2}-\mu_{1,1}=\mu_{2,2}-\mu_{2,1}$ and

$$
\mu_{1,3}-\mu_{1,2}=\mu_{2,3}-\mu_{2,2}
$$

## Equivalent statements

- The effect of $A$ depends upon $B$
- The effect of $B$ depends on $A$

$$
\begin{gathered}
H_{0}: \mu_{1,1}-\mu_{2,1}=\mu_{1,2}-\mu_{2,2}=\mu_{1,3}-\mu_{2,3} \\
H_{0}: \mu_{1,2}-\mu_{1,1}=\mu_{2,2}-\mu_{2,1} \text { and } \\
\mu_{1,3}-\mu_{1,2}=\mu_{2,3}-\mu_{2,2}
\end{gathered}
$$

## Three factors: A, B and C

- There are three (sets of) main effects: One each for A, B, C
- There are three two-factor interactions
- A by B (Averaging over C)
- A by C (Averaging over B)
- B by C (Averaging over A)
- There is one three-factor interaction: AxBxC

## Meaning of the 3-factor interaction

- The form of the $A \times B$ interaction depends on the value of $C$
- The form of the $A \times C$ interaction depends on the value of $B$
- The form of the $B \times C$ interaction depends on the value of $A$
- These statements are equivalent. Use the one that is easiest to understand.

## To graph a three-factor interaction

- Make a separate mean plot (showing a 2-factor interaction) for each value of the third variable.
- In the potato study, a graph for each oxygen level.

## Four-factor design

- Four sets of main effects
- Six two-factor interactions
- Four three-factor interactions
- One four-factor interaction: The nature of the three-factor interaction depends on the value of the 4th factor
- There is an $F$ test for each one
- And so on ...

## As the number of factors increases

- The higher-way interactions get harder and harder to understand
- All the tests are still tests of sets of contrasts (differences between differences of differences ...)
- But it gets harder and harder to write down the contrasts
- Effect coding becomes easier

## Effect coding

| Bact | $\mathbf{B}_{\mathbf{1}}$ | $\mathbf{B}_{\mathbf{2}}$ |
| :---: | :---: | :---: |
| 1 | 1 | 0 |
| 2 | 0 | 1 |
| 3 | -1 | -1 |

| Temperature | $\mathbf{T}$ |
| :---: | :---: |
| 1=Cool | 1 |
| 2=Warm | -1 |

$$
E(Y \mid \mathbf{X}=\mathbf{x})=\beta_{0}+\beta_{1} B_{1}+\beta_{2} B_{2}+\beta_{3} T+\beta_{4} B_{1} T+\beta_{5} B_{2} T
$$

## Interaction effects correspond to products of dummy variables

$E(Y \mid \mathbf{X}=\mathbf{x})=\beta_{0}+\beta_{1} B_{1}+\beta_{2} B_{2}+\beta_{3} T+\beta_{4} B_{1} T+\beta_{5} B_{2} T$

- The A x B interaction: Multiply each dummy variable for $A$ by each dummy variable for $B$
- Use these products as additional explanatory variables in the multiple regression
- The A x B x C interaction: Multiply each dummy variable for $C$ by each product term from the $A \times B$ interaction
- Test the sets of product terms simultaneously ${ }_{26}$

## Make a table

$$
E(Y \mid \mathbf{X}=\mathbf{x})=\beta_{0}+\beta_{1} B_{1}+\beta_{2} B_{2}+\beta_{3} T+\beta_{4} B_{1} T+\beta_{5} B_{2} T
$$

| Bact | Temp | $\mathrm{B}_{1}$ | $\mathrm{~B}_{2}$ | T | $\mathrm{~B}_{1} \mathrm{~T}$ | $\mathrm{~B}_{2} \mathrm{~T}$ | $E(Y \mid \mathbf{X}=\mathbf{x})$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| 1 | 1 | 1 | 0 | 1 | 1 | 0 | $\beta_{0}+\beta_{1}+\beta_{3}+\beta_{4}$ |
| 1 | 2 | 1 | 0 | -1 | -1 | 0 | $\beta_{0}+\beta_{1}-\beta_{3}-\beta_{4}$ |
| 2 | 1 | 0 | 1 | 1 | 0 | 1 | $\beta_{0}+\beta_{2}+\beta_{3}+\beta_{5}$ |
| 2 | 2 | 0 | 1 | -1 | 0 | -1 | $\beta_{0}+\beta_{2}-\beta_{3}-\beta_{5}$ |
| 3 | 1 | -1 | -1 | 1 | -1 | -1 | $\beta_{0}-\beta_{1}-\beta_{2}+\beta_{3}-\beta_{4}-\beta_{5}$ |
| 3 | 2 | -1 | -1 | -1 | 1 | 1 | $\beta_{0}-\beta_{1}-\beta_{2}-\beta_{3}+\beta_{4}+\beta_{5}$ |

## Cell and Marginal Means

|  | Bacteria Type |  |  |  |
| :--- | :---: | :---: | :---: | :---: |
| Tmp | 1 | 2 | 3 |  |
| 1=C | $\beta_{0}+\beta_{1}+\beta_{3}+\beta_{4}$ | $\beta_{0}+\beta_{2}+\beta_{3}+\beta_{5}$ | $\beta_{0}-\beta_{1}-\beta_{2}$ <br> $+\beta_{3}-\beta_{4}-\beta_{5}$ | $\beta_{0}$ <br> $+\beta_{3}$ |
| 2=W | $\beta_{0}+\beta_{1}-\beta_{3}-\beta_{4}$ | $\beta_{0}+\beta_{2}-\beta_{3}-\beta_{5}$ | $\beta_{0}-\beta_{1}-\beta_{2}$ <br> $-\beta_{3}+\beta_{4}+\beta_{5}$ | $\beta_{0}$ <br> $-\beta_{3}$ |
|  | $\beta_{0}+\beta_{1}$ | $\beta_{0}+\beta_{2}$ | $\beta_{0}-\beta_{1}-\beta_{2}$ | $\beta_{0}$ |

## We see

- Intercept is the grand mean
- Regression coefficients for the dummy variables are deviations of the marginal means from the grand mean
-What about the interactions?

$$
E(Y \mid \mathbf{X}=\mathbf{x})=\beta_{0}+\beta_{1} B_{1}+\beta_{2} B_{2}+\beta_{3} T+\beta_{4} B_{1} T+\beta_{5} B_{2} T
$$

## A bit of algebra shows

$\mu_{1,1}-\mu_{2,1}=\mu_{1,2}-\mu_{2,2}$ is equivalent to $\beta_{4}=\beta_{5}$
$\mu_{1,2}-\mu_{2,2}=\mu_{1,3}-\mu_{2,3}$ is equivalent to $2 \beta_{4}=-\beta_{5}$

$$
\text { So } \beta_{4}=\beta_{5}=0
$$

## Factorial ANOVA with effect coding is pretty automatic

- You don' t have to make a table unless asked
- It always works as you expect it will
- Significance tests are the same as testing sets of contrasts
- Covariates present no problem. Main effects and interactions have their usual meanings, "controlling" for the covariates.
- Could plot the least squares means

## Again

- Intercept is the grand mean
- Regression coefficients for the dummy variables are deviations of the marginal means from the grand mean
- Test of main effect(s) is test of the dummy variables for a factor.
- Interaction effects are regression coefficients corresponding to products of dummy variables.

## Balanced vs. Unbalanced Experimental Designs

- Balanced design: Cell sample sizes are proportional (usually equal)
- Explanatory variables have zero relationship to one another
- Numerator SS in ANOVA are independent.
- Everything is nice and simple
- Most experimental studies are designed this way.
- As soon as somebody drops a test tube, it's no longer true

## Analysis of unbalanced data

- When explanatory variables are related, there is potential ambiguity.
- $A$ is related to $Y, B$ is related to $Y$, and $A$ is related to B.
- Who gets credit for the portion of variation in Y that could be explained by either A or B ?
- With a regression approach, whether you use contrasts or dummy variables (equivalent), the answer is nobody.
- Think of full, restricted models.
- Equivalently, general linear test.

## Some software is designed for balanced data

- The special purpose formulas are much simpler.
- They were very useful in the past.
- Since most real data are at least a little unbalanced, these formulas are a recipe for trouble.
- Most textbook data are balanced, so they cannot tell you what your software is really doing.
- R's anova and aov functions are designed for balanced data, though anova applied to Im objects can give you what you want if you use it with care.
- SAS proc glm is much more convenient. SAS proc anova is for balanced data. Avoid it.

## Type I and Type III Tests

- proc glm displays both by default.
- Type III is the regression approach we know and love.
- We will use Type III and ignore Type I.
- But just for the record ...

## Tests based on Type III SS

- Type III Sums of squares are sequential.
- In order of the effects in the model statement.
- Numerator of F-ratio is $\left(\mathrm{SSR}_{\mathrm{F}}-\mathrm{SSR}_{\mathrm{R}}\right) / \mathrm{s}$, where the "restricted" model has all preceding terms, and the "full" model has those and also the effect being tested.
- First term is tested not controlling for anything.
- Second term is tested controlling for the first.
- Third term is tested controlling for the first two.
- And so on.
- But the denominator is MSE from the model with all effects.

## Type I vs. Type III

- Type I test controls for all preceding effects.
- Type III test controls for all other effects.
- Type I and Type III tests of the last effect in the model are identical.
- For balanced data, Type I and Type III tests of all effects are the same.
- I can't remember what the Type II tests are.
